PLATING POSTERS INC • METAL FINISHING REFERENCE SERIES

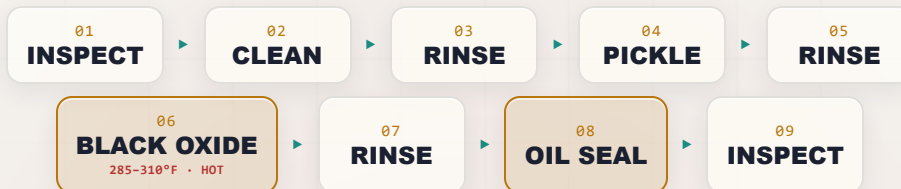

BLACK OXIDE

(STEEL)

THE COMPLETE TRAINING MANUAL

CONVERSION COATING • BLACKENING • OIL-SEALED

A full training course for the brand-new operator — from “what even is a conversion coating?” to a signed certificate of completion. The classic black finish on steel — true black magnetite grown in a boiling caustic bath, then sealed with oil. Thin, dimensionally neutral, matte-to-satin black: the finish on tools, fasteners, firearms, gears, and non-reflective optical parts. No electricity, no plating tanks, no mystery. Assumes you know nothing. Teaches you everything.

OPERATOR TRAINING & CERTIFICATION

EDITION 1.0 • 2026 • BEGINNER-FRIENDLY STYLE

Training reference only. Always verify exact parameters against your chemistry supplier's Technical Data Sheets (TDS), customer specifications, current Safety Data Sheets (SDS), and applicable OSHA, EPA, REACH, and local regulations before production use.

TABLE OF CONTENTS

READ FRONT-TO-BACK THE FIRST TIME · KEEP ON THE SHELF FOREVER AFTER

PART ONE — FRONT MATTER & FUNDAMENTALS

Welcome Aboard & How to Use This Manual	4
Learning Objectives	5
Ch 1 · What Is a Conversion Coating?	6
Ch 2 · What Is Black Oxide, and Why Do We Use It?	8
Ch 3 · The Three Temperature Classes (Hot, Mid, Cold)	12
Ch 4 · How a Hot Black Oxide Line Works	14
Ch 5 · Why the Order Matters (Walking the Line)	16
Ch 6 · Personal Protective Equipment (PPE)	20
Ch 7 · Emergency & First-Response	21
Ch 8 · The Safety Philosophy of a Boiling-Caustic Line	22

PART TWO — THE LINE, STATION BY STATION (STATIONS 01–09)

Station 01 · Inspect & Load	23
Station 02 · Alkaline Clean / Degrease	25
Station 03 · Rinse (Post-Clean)	27
Station 04 · Acid Pickle / Descale (As Needed)	29
Station 05 · Rinse (Post-Pickle)	31
Station 06 · Black Oxide — The Main Event (HOT)	32
Station 07 · Rinse (Post-Black-Oxide: Cold + Hot)	37
Station 08 · Oil / Wax / Lacquer Seal (Mandatory)	38
Station 09 · Inspect & Hand-Off	40

PART THREE — ACROSS THE LINE

The Three Temperature Classes Compared	41
Hot-Bath Operation: Boiling Caustic & the Steam-Eruption Hazard	42
Oil / Wax / Lacquer Sealing — Why It's Mandatory	44
Dimensional Neutrality — Black Oxide's Quiet Superpower	45
Decorative & Anti-Glare Uses	46
Specs: MIL-DTL-13924, AMS 2485, ASTM D769	47
Black Oxide on Other Metals (Stainless, Copper, Zinc)	48
Water, Rinse & Waste	49
Quality Checks	50
Troubleshooting Quick-Index	51
Glossary — Every Term, Plain and Simple	52
Operator Training Matrix (Template)	53

PART FOUR — BACK MATTER & CERTIFICATION

Completion Test (20 Questions)	54
Answer Key	56
Certificate of Completion	57

REMEMBER

This manual is a training and reference tool — **not** a substitute for your facility's written procedures, your supplier's TDS/SDS, or your supervisor's instructions. When this manual and your shop's official procedure disagree, **follow your shop's official procedure and ask your supervisor.**

WELCOME ABOARD

IF YOU DON'T KNOW A CONVERSION COATING FROM A COFFEE CUP, YOU ARE IN EXACTLY THE RIGHT PLACE

Welcome. If you're holding this manual, you're about to learn how to run — or at least understand — a **black oxide line**: the chemical process that turns bare steel a deep, even **black**, then seals it with oil. This is the classic black finish on hand tools and drill bits, on screws, bolts, and fasteners, on gears and bearings, on firearm parts, on automotive hardware, and on the non-reflective black parts inside cameras, scopes, and optical instruments. Maybe you started this week. Maybe you've been hanging parts for a year and finally want to know *why* you do the things you do. Either way, you're in the right place, and we're glad you're here.

Here's the most important thing we can tell you up front: **this manual assumes you know nothing about chemistry, metal finishing, or how steel turns black**. That's not an insult — it's a promise. Every term gets defined the first time we use it. Every step explains not just *what* to do but *why* it matters. Nobody is born knowing what "magnetite," "dimensional neutrality," or "the boiling point of a caustic bath" mean. You learn it. We're going to teach it — in the spirit of the *plain-language* guides: friendly, plain-spoken, and patient.

REMEMBER

You do not need to memorize this manual. You need to *understand* it. Understanding sticks. Memorizing fades by Friday.

HEADS-UP

Two big ideas before we start. (1) **A black oxide line has no electricity running through the parts** — no rectifier, no anode, no cathode. The black coating forms because the steel and the chemistry *react with each other*. (2) **The classic ("hot") black oxide bath is a tank of BOILING CONCENTRATED CAUSTIC running at about 285–310°F (141–154°C) — hotter than boiling water**. That bath is the single most dangerous thing in this building. It causes severe chemical *and* thermal burns, and it does something a pot of boiling water can't: if water gets into it, the water instantly flashes to steam and **erupts hot caustic out of the tank**. "No current" removes the shock hazard — it does **not** make this a safe line to take casually. We will hammer this lesson over and over, because it is the one that keeps you whole.

• HOW TO USE THIS MANUAL

The manual follows the **line itself**, station by station, in the order a part actually travels: inspect it, clean it, rinse it, pickle it (if it's scaled), rinse it, **black-oxide it (hot)**, rinse it, **oil/wax/lacquer it**, and inspect/hand it off. Reading it in order matters, because (as you'll soon learn) **the order of a finishing line is not random** — and neither is the order of this book.

THE ICONS — YOUR FRIENDLY MARGIN HELPERS

TIP

A shortcut or trick of the trade — the kind of thing a 20-year veteran would lean over and tell you.

REMEMBER

A core idea worth locking in. If you forget everything else on the page, don't forget these.

HEADS-UP

A safety warning. Read every one. We use them *liberally*, because a boiling-caustic line has real, serious hazards.

TECHNICAL STUFF

Deeper chemistry for the curious. Totally optional — skip it and you can still run the line.

FUN FACT

A bit of trivia to make the science stick (and give you something to say at lunch).

Two things you'll see at every station. Each station chapter ends with two recurring tools. The **Teach-Back** checklist is the set of things you must be able to *say out loud, unprompted* before you're cleared. The bordered **Sign-Off** box is the short statement your *trainer initials* once you've demonstrated the skill safely. Teach-Back is your study guide; Sign-Off is the gate.

WHAT YOU'LL BE ABLE TO DO

LEARNING OBJECTIVES

MASTER THIS FOUNDATION AND EVERY STATION CHAPTER CLICKS INTO PLACE

By the time you finish this manual, you should be able to confidently:

1. **Explain what a conversion coating is** in plain language — and how it differs from electroplating and anodizing.
2. **Describe what black oxide actually is** — a conversion coating that turns the steel's own surface into **black magnetite (Fe_3O_4)** by chemical reaction, with *no electric current*.
3. **Explain that black oxide is thin and dimensionally neutral** — roughly **0.5–2.5 micrometers (μm)**, adding almost no measurable thickness — and why that “no build-up” property is a major selling point for tight-tolerance parts.
4. **Name and tell apart the three temperature classes** — **hot** (boiling caustic-nitrate, true magnetite, the standard), **mid-temperature** (~200–250°F, also magnetite, less fuming), and **cold/room-temperature** (a selenium-based deposited film — *not* true magnetite, faster but thinner and less durable).
5. **State the central truth of black oxide:** the corrosion protection comes from the **OIL/WAX, not the oxide**. Bare black oxide barely resists rust; the mandatory oil, wax, or lacquer seal does the protecting.
6. **Name all nine stations of the hot line in order** and explain *why* the order cannot be rearranged.
7. **Recognize the main hazards** at each station — above all the **boiling caustic bath** (severe scald, and the water-flashes-to-steam eruption), plus hot caustic cleaner, acid pickle, nitrate/nitrite oxidizers, caustic mist, and the oil seal (mist, flammability, hot oil).
8. **Use the basic field checks** — the water-break test, color and coverage, the rub-off (smut) check, and corrosion testing **done with the oil applied**.
9. **Spot trouble early** — read a part and know whether the problem is upstream (cleaning/pickle), in the black oxide bath, in the rinse, or in the oil seal. Recognize **red haze / brown smut**.
10. **Talk the language** — use the right words with your lead, your chemist, and your chemistry supplier.

REMEMBER

You are not expected to hit all of these on day one. Surface finishing is a craft. The goal is steady competence, not instant mastery.

• THE NINE-STATION PROCESS AT A GLANCE

Here's the whole hot black oxide line in one strip: **Inspect** → **Clean** → **Rinse** → **Pickle** → **Rinse** → **BLACK OXIDE (HOT)** → **Rinse** → **OIL SEAL** → **Inspect**.

REMEMBER

Notice the pattern: **a rinse follows almost every working stage** — rinses keep one chemistry from poisoning the next, and (here especially) keep caustic from being carried out of the tank. And notice the *other* special rule: the **oil/wax/lacquer seal (08) is mandatory — never skipped**. A black-oxided part that hasn't been sealed is an unfinished, rust-prone part. There is no “bare black oxide” route out the door.

HEADS-UP

This nine-station layout is the **teaching** version of the **hot** process. Your shop may run a leaner line (some pickle steps are conditional, some lines use a duplex two-tank black oxide), or a **mid-temperature** or **cold** process entirely (Chapter 3 and Part Three). Always run *your* line's actual sequence and posted parameters.

WHAT IS A CONVERSION COATING?

THE TRUE BEGINNER'S PRIMER — SO FAR BACK WE DON'T EVEN ASSUME YOU KNOW WHAT "FINISHING" MEANS

THE ONE-SENTENCE VERSION

A conversion coating is a protective film you grow on a metal surface by making the metal itself react with a chemical solution — turning the top layer of the metal *into* the coating. That's the whole idea. Now let's unpack it, because the word "conversion" is doing a lot of work.

THREE COUSINS: PLATING, ANODIZING, AND CONVERSION COATING

If you've seen our other manuals, you've met two other finishing families. Lining all three up side by side is the key to understanding black oxide.

- **Electroplating** *adds* a layer of a *different* metal on top of your part, using **electricity**. Electricity drives dissolved metal (like zinc or nickel) out of a bath and onto the part. The coating is a brand-new metal skin sitting *on* the original surface — and it *adds thickness*.
- **Anodizing** *converts* the part's *own* surface into a thick, hard oxide — but it still uses **electricity** to drive the reaction, and it only works on metals like aluminum.
- **Conversion coating** (this manual) *converts* the part's own surface into a thin protective film using **only chemistry** — **no electricity at all**. You dunk the part, the surface reacts with the solution, and a new compound forms right where the bare metal used to be. For black oxide, that new compound is **black iron oxide (magnetite)**.

REMEMBER

Lock in the difference: **Plating adds a new metal with electricity. Anodizing converts the surface with electricity. A conversion coating converts the surface with chemistry alone — no rectifier, no anode, no cathode, no current.** If you ever go looking for the "power supply" feeding the parts on a black oxide line, you won't find one. That's not a missing piece — that's the whole point.

FUN FACT

Black oxide is one of the oldest metal finishes still in daily use. Gunmakers have "blacked" steel for well over a century — the old hand method of repeatedly heating, oxidizing, and oiling steel to build a black, rust-resistant skin is the ancestor of the modern tank process. The chemistry got faster and the tanks got hotter, but the idea is the same one a 19th-century gunsmith would recognize: turn the steel's own surface black, then feed it oil.

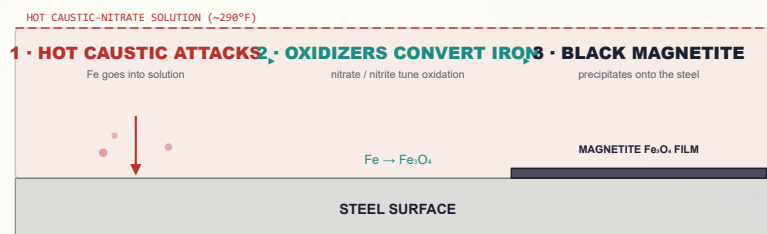

HOW A CONVERSION COATING FORMS — NO CURRENT REQUIRED

So if there's no electricity pushing metal around, what makes the coating appear? The metal and the solution do it themselves. Here's the plain-language version for hot black oxide:

1. The black oxide solution is a **hot, concentrated caustic** (sodium hydroxide) bath with **oxidizers** (nitrates and/or nitrites) dissolved in it, running **near 290°F**. When clean bare steel enters it, the hot caustic begins to attack the iron at the surface, taking it into solution as soluble iron compounds.
2. The dissolved oxidizers immediately **oxidize that iron** to higher oxidation states, controlling exactly *how much* oxygen the iron picks up.
3. Right at the surface, the dissolved iron compounds react and **precipitate as a tightly-bonded layer of black iron oxide — magnetite, Fe_3O_4** — growing into the surface where the bare steel used to be.

The result is an **integral** coating — chemically grown out of the steel itself, not glued on top — and it's a hard, adherent, matte-to-satin **black**. But it is also **thin and porous**, which is why (as you'll hear constantly) it must be sealed with oil.

HOW THE FILM FORMS (NO ELECTRICAL CELL)

No electricity — the hot caustic and oxidizers do it themselves.

TECHNICAL STUFF

Roughly: hot caustic dissolves surface iron as soluble sodium ferrite/hypoferrite species; the nitrate/nitrite oxidizers tune the iron's oxidation state so that **magnetite, Fe_3O_4** (a mixed $\text{Fe}^{2+}/\text{Fe}^{3+}$ oxide — the same black, magnetic oxide as natural lodestone and the black scale on a blacksmith's anvil) precipitates as the stable surface phase. Get the chemistry wrong — too little oxidizer, exhausted bath, wrong concentration — and you grow the *wrong* iron oxides (reddish Fe_2O_3 -type smut, the "red haze") instead of clean black magnetite. That is why bath control is everything on this line.

HEADS-UP

"No electricity at the part" removes the shock-at-the-tank hazard — but pumps, heaters (which hold the bath above the boiling point of water), hoists, and ventilation are still serious electrical equipment, and **the bath is hotter than boiling water and full of caustic**. Any maintenance still requires **Lockout/Tagout (LOTO)** — and a "locked-out" black oxide tank can still scald you for a long time after the power is off.

CHAPTER 2

WHAT IS BLACK OXIDE?

THIN, BLACK, DIMENSIONALLY NEUTRAL — THE “BLACKENING” CONVERSION COATING FOR STEEL

• BLACK OXIDE’S JOB: A THIN BLACK FINISH — SEALED BY OIL

Iron phosphate (our other manual) is a paint base. Manganese phosphate is a heavy wear-and-oil coating. **Black oxide is different from both — it’s a thin *blackening* conversion coating.** Its jobs are:

- **Appearance** — a uniform, attractive matte-to-satin **black** (decorative, and a uniform look across mixed steel parts).
- **Mild corrosion resistance** — but *only once it’s sealed with oil, wax, or lacquer* (this is the part everyone gets wrong; see below).
- **Glare reduction** — black oxide is **anti-reflective**, which is why it’s the finish on optical and sighting parts, camera internals, and tooling where you don’t want glints.
- **Dimensional neutrality** — it adds almost no thickness, so it can go on close-tolerance parts (gears, gauges, precision fasteners) that plating would throw out of spec.

★

REMEMBER
Black oxide is a thin blackening conversion coating, and its corrosion protection comes from the OIL/WAX/LACQUER — not the oxide. Bare black oxide is mostly cosmetic and gives only minimal rust protection on its own. The magnetite layer is a thin, porous, black *carrier*; the oil that fills its pores is what actually fights corrosion. “Black oxide” as a finished product really means “**black oxide + oil**.” Never think of the seal as optional.

A WHISPER-THIN BLACK SKIN GROWN INTO THE STEEL

OIL / WAX SEAL — fills the pores

BLACK MAGNETITE Fe₃O₄ (porous, ~0.5–2.5 μm)

STEEL SUBSTRATE

← does the protecting

← deepens the black

Its corrosion protection comes from the oil — not the bare oxide.

• WHAT BLACK OXIDE IS — MAGNETITE, AND THIN

- It is **magnetite, Fe_3O_4** — black iron oxide, grown chemically out of the steel surface (in the hot and mid-temp processes). (*The cold process is different — a deposited selenium-based film, not true magnetite. See Chapter 3.*)
- It is **thin — roughly 0.5–2.5 μm (micrometers)**. For comparison, a human hair is about 70 μm across. Black oxide is a *whisper* of a coating.
- It is **essentially dimensionally neutral**. Because it grows partly *into* the steel and is so thin, the net dimensional change is tiny — often well under a ten-thousandth of an inch. On most parts you cannot measure a meaningful size change.
- It is **matte-to-satin black**, not bright/shiny like chrome or bright nickel. The final depth of black and the sheen are strongly influenced by the **oil** that seals it.

REMEMBER

Dimensional neutrality is black oxide's quiet superpower. A plated part *grows* by the plating thickness; a phosphated part grows a measurable coating; a **black-oxidized part is, for practical purposes, the same size it went in**. That's why precision parts — gears, gauges, bearings, tight-tolerance fasteners, optics hardware — are blacked rather than plated. (Full section in Part Three.)

HEADS-UP — YOU DON'T READ BLACK OXIDE LIKE AN IRIDESCENT PHOSPHATE

Iron phosphate shows blue-to-gold iridescence; you read black oxide by **uniform deep black color, full coverage, no red/brown smut or haze, and how well it took oil**. A good one is an even, uniform black with no bare or brown spots, no loose rub-off powder, and an oiled surface that beads/sheds water.

FUN FACT

The black oxide on a part is the same chemical — magnetite — as the dark “mill scale” on hot-rolled steel and the black skin a blacksmith hammers onto hot iron. The difference is *control*: a black oxide bath grows a thin, even, adherent magnetite layer on purpose, instead of the thick, flaky, uneven scale you get from random heating. Same compound, engineered.

• WHERE YOU’LL SEE IT (TYPICAL PARTS)

- **Tools and tooling** — drill bits, taps, end mills, hand tools, punches, dies, jigs.
- **Fasteners** — screws, bolts, nuts, washers, studs (uniform black, no dimensional growth that would bind threads).
- **Firearms** — receivers, barrels, small parts (a traditional black, glare-free, oiled finish; closely related to historical “bluing”).
- **Gears, bearings, shafts, and precision machine parts** — where tolerances rule out plating.
- **Automotive hardware** — brackets, clips, springs, trim hardware.
- **Optical / non-reflective parts** — camera and scope internals, sighting components, instrument parts — black oxide kills glare.

REMEMBER

Black oxide is generally **NOT a paint base**. Its purpose is decorative black + mild (oil-sealed) corrosion resistance + glare reduction + dimensional neutrality. If the customer wants paint or powder, the right tool is a phosphate pretreatment — not black oxide.

• IT’S A STEEL PROCESS — KNOW YOUR SUBSTRATE

Classic black oxide is built from the **iron in the part**, so it’s a **steel/iron** process: carbon steel, alloy steel, cast iron, and hardened steel are its home turf. **Stainless steel, copper/brass, and zinc each need a different blackening chemistry** (Part Three) — the carbon-steel caustic bath would not blacken them correctly, and it actively attacks zinc. If one of those metals shows up on the line, flag it; don’t run it.

TIP

When a traveler calls out a black finish on a non-steel part (a stainless bracket, a brass fitting, a zinc-plated screw), stop and confirm the process with your lead. “Black oxide” is a family of different chemistries by metal — running the wrong one ruins the part.

• THE HONEST TRADEOFFS

A good operator knows the weaknesses too:

- **Bare coating barely resists corrosion.** Without the oil/wax/lacquer it will rust — fast. The seal is mandatory, full stop.
- **Corrosion protection is modest even when sealed** — black oxide + oil is good indoor/handling protection and a fine decorative finish, but it is **not** in the league of zinc plating or heavy zinc phosphate for outdoor or harsh service.
- **The hot process is dangerous.** A tank of boiling caustic at ~290°F is the most hazardous thing in the shop (Chapters 6–8).
- **It's a steel/iron process.** Stainless, copper/brass, and zinc each need *different* black-oxide chemistries. This manual is steel.
- **Color depends on good chemistry and good cleaning.** Poor cleaning or an out-of-balance bath gives brown smut, red haze, gray patches, or rub-off.
- **Waste streams are regulated** — high-pH caustic, nitrate/nitrite, oily waste (and, for the cold process, **selenium**, which is toxic and tightly regulated).

REMEMBER

You've got the "why" now: a conversion coating grown by chemistry alone, thin and dimensionally neutral, **black magnetite** on steel, read by uniform black color and coverage (not iridescence), and protected by a **mandatory oil seal**. Keep that picture in your head and every station ahead will make sense.

TECHNICAL STUFF

Why is bare magnetite such a weak corrosion barrier when it's the same compound as protective mill scale? Because the thin black oxide layer is **porous** — it's riddled with microscopic channels down to the steel. Left open, those pores wick in moisture and the steel rusts underneath. The oil/wax fills and blocks those pores; that's the entire mechanism of black oxide corrosion protection. No oil, open pores, fast rust.

THE THREE TEMPERATURE CLASSES

THREE WAYS TO TURN STEEL BLACK — AND ONE OF THEM ISN'T REALLY MAGNETITE

There is no single “black oxide process.” There are three families, sorted by **temperature**. You must know all three, because they behave, protect, and *hazard* very differently.

• 1. HOT BLACK OXIDE — THE CLASSIC STANDARD

- **What it is:** a **boiling alkaline caustic-nitrate bath** — concentrated sodium hydroxide plus nitrate/nitrite oxidizers — running at about **285–310°F (141–154°C)**.
- **What it grows:** **true black magnetite (Fe_3O_4)**, grown chemically out of the steel.
- **Why it's the standard:** best adhesion, deepest/most uniform black, best durability and abrasion resistance, best corrosion resistance (once oiled). This is what most specs mean by “black oxide on steel.”
- **The catch:** the bath is the **standout hazard** — boiling concentrated caustic, severe burns, and the water-flash-to-steam eruption risk. This whole manual's safety spine is built around it.

• 2. MID-TEMPERATURE BLACK OXIDE

- **What it is:** an alkaline oxidizing process running cooler — roughly **200–250°F** — usually proprietary chemistries with less free caustic.
- **What it grows:** still **magnetite** (true black oxide), so the finish quality is much closer to hot than to cold.
- **Why shops use it:** **less caustic fuming and a lower (though still hot) temperature** than the boiling hot bath — a safer, lower-maintenance alternative when the very best hot-bath performance isn't required.
- **The catch:** still hot enough to scald; still caustic. Easier than hot, but not “safe.”

• 3. ROOM-TEMPERATURE / COLD BLACK OXIDE

- **What it is:** an **ambient-temperature** process — no heating.
- **What it grows — the key accuracy point:** **NOT true magnetite**. Cold blackening deposits a **selenium-based conversion film** (a copper-selenide / selenium-bearing black layer formed from selenious acid and copper salts). It blackens the surface chemically, but it is a *deposited selenide film*, not grown magnetite.
- **Why shops use it:** **fast, easy, no heat, no boiling-caustic hazard, low equipment cost** — great for **touch-up**, field/in-house blackening, repair of bare spots, and low-demand work.
- **The catch:** **thinner, less durable, less abrasion-resistant, and less corrosion-resistant** than hot/mid magnetite. And it carries its own hazard: **selenium is toxic and its waste is regulated**. It still needs an oil seal.

★

REMEMBER

Don't confuse the three. **Hot and mid-temperature grow real black magnetite (Fe₃O₄).** Cold/room-temperature is a different chemistry entirely — a **selenium-based deposited film, not magnetite** — faster and safer to apply but thinner and less durable. If someone asks “is cold blackening the same as hot black oxide?” the honest answer is: same *look*, different *chemistry*, lower *performance*.

CLASS	TEMP	WHAT IT GROWS	PROS	CONS
Hot	285–310°F	True magnetite (Fe ₃ O ₄)	Best black, adhesion, durability, corrosion (oiled); the standard	Boiling caustic — worst hazard ; energy-hungry; fuming
Mid-temp	~200–250°F	True magnetite (Fe ₃ O ₄)	Less fuming, lower temp than hot; good finish	Still hot/caustic; often proprietary
Cold / room-temp	~ambient	Selenium-based film (NOT magnetite)	Fast, no heat, cheap, great for touch-up	Thinner, less durable; selenium waste ; lower corrosion resistance

⚠

HEADS-UP

All three still **require the oil/wax/lacquer seal**. None of them — not even the hot magnetite — gives meaningful corrosion protection bare. The seal is universal across all three classes.

⚙

TECHNICAL STUFF

The hot and mid baths sit on the alkaline-oxidizing branch of iron chemistry: caustic + nitrate/nitrite drive surface iron to the magnetite phase. The cold process sits on a completely different branch — an **immersion/displacement** reaction in which selenious acid and copper ions deposit a dark copper-selenide conversion film on the steel. That's why cold “black oxide” is, strictly, a misnomer: it's a *black conversion coating*, but chemically it isn't iron oxide at all. The military spec MIL-DTL-13924 reflects this by defining different **classes** for different substrates/temperatures (verify the exact current class definitions against the spec — see Part Three).

☀

FUN FACT

Cold blackening is the bottle of dark liquid you'll find in a gunsmith's or machinist's drawer for touching up a worn spot in the field — wipe it on, it turns black in seconds, wipe off, oil it. Convenient and impressive — but it's a thin selenide film, not the tough grown magnetite of a hot tank. Right tool for a touch-up, wrong tool for a spec job.

CHAPTER 4

HOW A HOT BLACK OXIDE LINE WORKS

THE BIG PICTURE — A LINE IS A SYSTEM, NOT A PILE OF SEPARATE TANKS

A hot black oxide line is not one tank. It's a **sequence of stages** a part travels through in a strict order — clean, rinse, (pickle), rinse, black oxide, rinse, oil — like a dishwasher cycle where each station does one chemical job and prepares the surface for the next. Black oxide is almost always run by **immersion (dip)** in baskets or on racks/hoists, not spray:

- **Immersion (dip).** Parts are lowered into a series of tanks in sequence. This is standard for black oxide because the working bath is **hot and caustic** (you cannot safely spray a boiling caustic solution — it would throw caustic mist everywhere) and the coating builds over minutes of dwell.

**TIP**

If you've worked a spray paint-prep washer, unlearn that rhythm here. Black oxide is a **hot, deep-dwell dip process**. Parts sit fully immersed in the hot bath for several minutes. Plan for fewer, bigger, deliberate batches handled with a hoist — not a fast conveyor.

• THE DEFINING FEATURES OF A HOT BLACK OXIDE LINE

Two things define this line and set it apart:

1. **The black oxide bath BOILS — and it boils HOTTER than water.** Iron phosphate is warm; even manganese phosphate “near boiling” is ~190–210°F. A hot black oxide bath runs **~285–310°F** — *above* water's 212°F boiling point. It can boil that hot precisely *because* it is concentrated caustic (see the next page). The heat is what grows the magnetite, and it is the source of the line's worst hazard.
2. **The oil/wax/lacquer seal is mandatory.** There is no “paint route” and no “ship it bare” route. *Every* black-oxidized part is sealed. The combination “black oxide + oil” is the actual product.

**REMEMBER**

The two memory hooks for this line: **(1) the bath boils hotter than water because it's concentrated caustic** — which is exactly why water dripped into it flashes to steam, and **(2) the oil seal is never skipped**. Burn both in now and the rest of the manual is just detail.

**FUN FACT**

Add enough salt to water and you raise its boiling point — the same reason salted pasta water runs a touch hotter. A black oxide bath takes that to an extreme: so much caustic is dissolved that the water can't boil until it's nearly 100°F hotter than a plain pot on the stove.

WHY THE BATH BOILS ABOVE 212°F (AND WHY THAT’S THE HAZARD)

Pure water boils at 212°F (100°C). When you dissolve a large amount of a salt like sodium hydroxide in water, the **boiling point goes up** — the more concentrated, the hotter it must get to boil. A hot black oxide bath is so concentrated in caustic that it boils at **~285–310°F**. As the bath runs all day, water evaporates, the bath gets *more* concentrated, and the boiling point **climbs even higher**. You bring it back down by **carefully adding water** to restore the level and concentration.

⚠

HEADS-UP — THE SINGLE MOST IMPORTANT SAFETY LESSON IN THIS MANUAL

Because the bath sits far above water’s boiling point, **any water that hits it instantly flashes to steam**. A cup of water dumped in, a wet tool, a dripping hose, condensation, or rain through a roof leak can cause a violent **eruption** that throws boiling caustic out of the tank and onto anyone nearby. **NEVER add water quickly to a hot caustic black oxide bath**. Water additions to control the bath are done **slowly, carefully, in small amounts, with the operator clear of the splash zone, exactly per written procedure** — never as a fast dump, and never from a careless hose. Keep all stray water (other tanks, hoses, drinks, leaks) away from this tank. We will repeat this at Station 06 and in Part Three, because it is the lesson that prevents the worst injury on the line.

THE WHOLE SEQUENCE: 9 STATIONS (TEACHING LAYOUT)

#	STATION	THE ONE THING IT DOES	TEMP	TIME
01	Inspect & Load	Confirms the part & racks it for full contact and drainage	Ambient	—
02	Alkaline Clean	Removes oil, grease, soil so chemistry can touch bare steel	120–180°F	5–10 min
03	Rinse (Post-Clean)	Washes off cleaner before pickle/black oxide	Ambient	30–60 s
04	Acid Pickle / Descale (as needed)	Removes rust/scale/oxide so steel is bare and reactive	Amb-warm	per TDS
05	Rinse (Post-Pickle)	Removes acid before the caustic bath	Ambient	30–60 s
06	Black Oxide (HOT)	Grows the black magnetite coating	285–310°F	5–20 min
07	Rinse (Post-Black-Oxide)	Removes/neutralizes caustic carryover (cold + hot rinse)	Amb / hot	1–2 min
08	Oil / Wax / Lacquer Seal	Fills the pores — mandatory corrosion + finish	Amb-hot	1–10 min
09	Inspect & Hand-Off	Confirms color/coverage/rub-off/oil; sends part out	Ambient	—

★

REMEMBER

Every stage either protects the next stage or poisons it. There is no neutral step. A part that leaves the cleaner still oily blackens patchy or brown. A part that drags acid into the caustic bath upsets it (and acid-into-caustic is a violent, heat-releasing mismatch). A part that drags caustic out of the black oxide tank without rinsing leaves residue and future corrosion. A part that skips the oil will rust within hours. Station 04 (pickle) is *conditional*; Station 08 (oil) is *never* skipped.

CHAPTER 5

WHY THE ORDER MATTERS

WALKING THE LINE — EACH STAGE SETS UP THE NEXT, AND THE SEQUENCE IS LOCKED BY CHEMISTRY

You might think the stage order is just convention. It isn't. Each stage exists *because of* the stage before and after it. Here's the logic, link by link.

STATION 02 — CLEAN: GET RID OF THE JUNK FIRST

The blackening reaction needs to touch **bare steel**. Oil, grease, machining coolant, fingerprints, and shop soil block it. **Black-oxide over oil and you've blackened nothing** — you get patchy, brown, gray, or uneven results wherever soil remains. There's a free, foolproof check called the **water-break test**: pull a cleaned part and watch the water. A smooth, continuous, unbroken sheet means clean; beading like rain on a waxed car means oil remains — re-clean.

**TIP**

The simplest, most powerful quality check in the whole shop is the **water-break test**, and it's free. Continuous sheet = clean. Beading = oil still there → stop and re-clean. On black oxide, invisible oil is the #1 cause of patchy or brown coatings.

**HEADS-UP**

The cleaner is **hot and alkaline (caustic)** — it causes chemical burns and can seriously injure your eyes. Full PPE, and know where your shower and eyewash are *before* you need them.

STATION 03 — RINSE (POST-CLEAN): DON'T CARRY THE CLEANER FORWARD

The cleaner is alkaline. If the next step is an **acid pickle**, dragging alkaline cleaner into acid neutralizes and contaminates the pickle. The rinse strips the cleaner film off first.

**REMEMBER**

Rinses exist to keep each chemistry from invading the next stage. This is a firewall — not a rest stop.

STATION 04 — ACID PICKLE / DESCALE (AS NEEDED): BARE, REACTIVE STEEL

Black oxide grows on **clean, bare, oxide-free steel**. If parts arrive rusty, scaled, or carrying heat-treat oxide, the cleaner won't remove that — you need an **acid pickle** (typically a dilute mineral acid such as hydrochloric or sulfuric, per the supplier TDS) to strip rust and scale down to bright steel. On clean, already-bright stock this step is skipped.

HEADS-UP

The pickle is **acid** — corrosive to skin, eyes, and lungs; it can also generate hydrogen and (on some alloys) fumes. Wear full acid PPE. And remember: **acid and the downstream caustic bath are chemical opposites — never let them mix in bulk**. That's exactly why Station 05 (rinse) sits between them.

TECHNICAL STUFF

Aggressive acid pickling of high-strength steels can introduce **hydrogen embrittlement** risk. For high-strength or hardened parts, follow the spec's pickling limits and any required **post-bake** for hydrogen relief. When in doubt, ask your chemist/engineer — this is a real structural-safety issue, not just cosmetics.

STATION 05 — RINSE (POST-PICKLE): DON'T CARRY ACID INTO CAUSTIC

A pickled part is wet with acid. Drag that into the boiling caustic black oxide tank and you neutralize/contaminate the bath and add an unwanted, heat-releasing acid-base reaction in a tank you never want surprises in. Rinse it off first.

REMEMBER

"Drag cleaner into acid and you kill the pickle; drag acid into caustic and you wound the black oxide bath." The rinses on either side of the pickle are not optional.

TIP

Over-pickling is its own defect — it roughens the steel and (on high-strength parts) raises the embrittlement risk. Pickle *just* long enough to reach bright, bare steel, then move on. More time is not more better.

STATION 06 — BLACK OXIDE (HOT): THE MAIN EVENT

Now — and only now, with a clean, bare, oxide-free, well-rinsed steel surface — the conversion coating actually forms, in the **boiling caustic-nitrate bath**. The hot caustic attacks the iron; the oxidizers control its oxidation; black **magnetite** precipitates onto the surface. This is the payoff stage — and the most dangerous one.

HEADS-UP — THE STANDOUT HAZARD ON THIS LINE

The black oxide bath is **boiling concentrated caustic at ~285–310°F (141–154°C) — hotter than boiling water**. A splash, a dropped part that displaces solution, or leaning over the tank can cause **severe, instant chemical-AND-thermal burns**. Worse, **water in any form flashes to steam on contact and can erupt boiling caustic out of the tank**. Lower and lift parts **slowly** with a hoist (never drop them in). Make sure parts and baskets aren't carrying pooled water into the tank. **Never add water fast; never dump water in; keep hoses, drains, and leaks away**. Keep your face and body back, run the ventilation, and wear full PPE including a **face shield** and **caustic- and heat-rated gloves and apron**. Treat the edge of this tank like a vat of boiling oil that also burns chemically.

HEADS-UP — CAUSTIC MIST + NITRATE/NITRITE OXIDIZERS

Beyond the heat, the bath throws **caustic mist** (don't breathe it — run local exhaust) and contains **nitrate/nitrite oxidizers**. Keep the oxidizer chemistry away from fuels, oils, rags, and incompatible chemicals, and never combine chemistries on your own.

STATION 07 — RINSE (POST-BLACK-OXIDE): GET THE CAUSTIC OFF

The part leaves the black oxide tank coated in clinging hot caustic. That must be rinsed off thoroughly (commonly a **cold rinse then a hot rinse**) — leftover caustic causes white residue, blotchy color, and corrosion under the oil later. A hot final rinse also warms the part so it flash-dries and takes oil better.

REMEMBER

Caustic residue under oil is a future corrosion spot — and a contact hazard for whoever handles the “finished” part. This rinse is the wall between the boiling-caustic bath and the oil. Rinse thoroughly.

STATION 08 — OIL / WAX / LACQUER SEAL: THE MANDATORY FINISH

This is **not optional**, and there is **no alternative route**. Bare black oxide gives only minimal corrosion resistance — left unsealed, it will rust quickly. The **oil, wax, or lacquer** penetrates the porous magnetite, seals it, **provides the corrosion protection**, and **deepens the black** to its final rich appearance. The coating is the *carrier*; the seal is the *protection*.

REMEMBER

On a black oxide line the seal step is mandatory and central — never skip it. The magnetite without a seal is an unfinished, rust-prone part. “Black oxide + oil” is the actual product. Choice of seal sets the result: thin water-displacing oil for handling/indoor parts; heavier oil or **wax** for better protection; **lacquer/topcoat** for a dry, durable black.

HEADS-UP

The seal station adds **oil-mist, flammability, and (if hot) hot-oil** hazards. Keep ignition sources away, control mist with ventilation, follow the seal product’s TDS for temperature, and **never plunge a dripping-wet part into a hot-oil tank** — trapped water flashes to steam there too.

STATION 09 — INSPECT & HAND-OFF: SEND IT OUT RIGHT

A final look confirms uniform deep black, full coverage, no red haze/brown smut, minimal rub-off, and a properly sealed (oiled) surface — then it ships. This is the last chance to catch a problem before the part reaches the customer.

REMEMBER

The whole nine-station sequence is one logic chain: *clean it so the magnetite can grow* → *rinse so cleaner doesn’t kill the pickle* → *pickle (if needed) so steel is bare* → *rinse so acid doesn’t wound the caustic bath* → *black-oxide (hot) to grow the magnetite* → *rinse so caustic doesn’t corrode under the oil* → *oil/wax/lacquer (mandatory) to protect and finish* → *inspect so nothing bad ships*. Skip the clean and you get brown patches; skip the seal and the part rusts.

TIP

When you understand *why* each stage exists, troubleshooting becomes logical. Brown/red smutty or hazy parts? Look at cleaning, bath concentration, and bath age. Gray/patchy black? Cleaning, pickle, or a weak/cold bath. Rust after coating? Caustic rinse and the oil step. Rub-off powder? Bath imbalance/contamination. The defect almost always points back to the stage that was supposed to prepare for it.

CHAPTER 6

PPE — YOUR DAILY ARMOR

THE GEAR THAT STANDS BETWEEN YOU AND A TANK OF BOILING CAUSTIC

A hot black oxide line works with hot alkaline cleaners, **acid pickle**, a **boiling caustic-nitrate bath**, nitrate/nitrite **oxidizers**, caustic mist and steam, oils and waxes (some hot), and slick wet floors. None of these will hurt you if you respect them and wear the right gear. Several can hurt you badly — **the boiling caustic bath fastest and worst of all**.

★ REMEMBER
There is no part, no order, and no deadline worth an injury. Scrap can be reworked. Your skin and eyes cannot. On this line the boiling caustic bath earns extra respect: it can scald you in the time it takes to read this sentence, and it can erupt if water reaches it.

• THE MASTER PPE SET (WEAR ON THE LINE)

- **Chemical splash goggles** — sealed goggles, not safety glasses.
- **Face shield** — over the goggles for any work near the **boiling caustic bath**, the hot cleaner, the pickle, charging/dumping tanks, or a hot-oil dip. **Mandatory at the black oxide tank.**
- **Caustic/acid- AND heat-resistant gloves** — elbow-length, rated for caustics and acids; for hot-bath and hot-basket handling you also need **heat resistance**. Inspect for pinholes before each use.
- **Chemical-resistant apron** — full-length (a splash of boiling caustic is both a chemical *and* thermal burn).
- **Chemical-resistant, non-slip boots** — floors around hot tanks and oil stations are wet, slick, and sometimes oily.
- **Long sleeves / appropriate clothing** — no exposed skin where hot splashes, steam, or caustic mist are likely.
- **Proper hoists/tools** so you never reach over the boiling bath by hand.

⚠ HEADS-UP — RESPIRATORY PROTECTION
Required when ventilation is inadequate or when working over/near the **steaming caustic bath** (caustic mist), the alkaline cleaner, the acid pickle, the nitrate/nitrite oxidizers, or **oil mist**. If you can see steam/mist rising off the bath or smell acid, cleaner, or oil, ventilation isn't keeping up — stop and report it.

• STATION-BY-STATION HAZARD SUMMARY

STATION	PRIMARY HAZARD	WHY IT'S DANGEROUS
01 Inspect/Load	Sharp/heavy parts; pinch points; hoists	Cuts, crush, caught-in
02 Alkaline Clean	Hot caustic (120–180°F), mist	Chemical burns; eye injury; respiratory irritation
03 Rinse	Residual cleaner; wet floor	Mild irritant; slips
04 Acid Pickle	Acid, fumes, possible hydrogen	Chemical burns; respiratory irritation
05 Rinse	Acid residue; wet floor	Mild irritant; slips
06 Black Oxide	BOILING CAUSTIC (~285–310°F); steam; water-flash eruption; caustic mist; oxidizers	Severe scald + chemical burns (worst hazard); eruption if water enters; inhalation; fire risk
07 Rinse	Caustic residue; hot water; wet floor	Caustic burns; scald; slips
08 Oil/Wax/Lacquer	Oil mist; flammability; hot oil if heated ; solvent	Fire; burns; slips; inhalation
09 Inspect/Hand-Off	Hot/oily parts; sharp edges	Burns; slips; cuts

⚠ HEADS-UP
Never eat, drink, smoke, vape, or apply cosmetics on the line. Hand-to-mouth contact ingests process chemicals. Wash thoroughly before breaks and before leaving. Smoking is doubly forbidden near the oil station (flammable) and near the oxidizers.

CHAPTER 7

EMERGENCY & FIRST-RESPONSE

KNOW THESE BEFORE YOUR FIRST SHIFT, NOT DURING YOUR FIRST INCIDENT

**HEADS-UP**

Memorize the location of the nearest **eyewash, safety shower, fire extinguisher, spill kit, first-aid kit, and emergency exit** *before* you start work. In an emergency you won't have time to go looking. On this line, also know exactly **where the boiling caustic tank is and how to move around it safely.**

• FIRST RESPONSE BY HAZARD

SITUATION	WHAT TO DO — IMMEDIATELY
Boiling-caustic splash (the big one)	Get it off fast : flush with copious cool water at the safety shower for at least 15–20 minutes (caustic burns keep going); remove contaminated clothing while flushing; do not peel clothing stuck to a burn; get medical help. At ~290°F it's a thermal <i>and</i> chemical burn.
Caustic in eyes	Straight to the eyewash, hold eyelids open, flush at least 15–20 minutes , get medical help. Caustic eye burns are emergencies.
Acid (pickle) on skin or in eyes	Same: remove clothing, flush 15 min (eyes at eyewash), get help. Don't "wipe and continue."
Inhaled caustic mist/steam/acid fumes/NOx	Get to fresh air immediately; report it. Tell medical staff what you were near.
Bath eruption (water got in)	Evacuate the splash zone immediately; do not approach until it settles and a lead clears it; treat any contact as a caustic splash above. Report the cause (where did the water come from?).
Hot-oil burn or hot part	Cool with water; don't peel stuck clothing; get medical help for anything beyond minor.
Oil fire	Correct extinguisher (Class B for oils); never water on a hot-oil fire; evacuate and call for help per your plan.
Spill	Only clean up small spills you're trained for, in PPE. Caustic and acid are opposites — never just mix them. Keep oxidizers away from fuels/oils.

**REMEMBER**

When in doubt, **flush, then ask**. Water and time fix most chemical and thermal contact *on your skin* if you act fast — but remember the cruel twist of this line: **water on your skin = good; water in the bath = eruption**. Report every incident, even "minor" ones.

**HEADS-UP — LOCKOUT/TAGOUT (LOTO)**

No current through the parts, but the pumps, **heaters** (holding the bath above water's boiling point), hoists, filters, and ventilation are serious electrical equipment. **LOTO is mandatory before any maintenance** — and a locked-out black oxide tank stays **scalding and caustic** long after the power is off. Let it cool, or treat it as hot, before service.

**FUN FACT**

The 15-minute flush rule isn't arbitrary — it's the time emergency-response standards found necessary to dilute and carry away most corrosive chemistry before deep tissue damage. With caustic you often flush *longer*, because alkalis penetrate tissue and keep reacting.

CHAPTER 8

THE SAFETY PHILOSOPHY OF A BOILING-CAUSTIC LINE

THE MOST DANGEROUS BATH IN THE SHOP DESERVES THE MOST DISCIPLINED HABITS IN THE SHOP

People sometimes assume that because there's no high-amperage rectifier at the parts, a conversion-coating line is "the safe one." That's a dangerous assumption — and especially dangerous here, because **this is the hottest, most aggressive bath in the building**. The hazards just *moved*:

- **The bath is boiling caustic above water's boiling point — heat AND caustic are the headline hazard.** The black oxide bath is the worst: severe scald *and* chemical burns, instantly.
- **Water and the bath are mortal enemies.** The signature hazard of this line — found on almost no other line in the shop — is **water flashing to steam and erupting the tank**. Controlling water around this tank (additions, wet parts, hoses, leaks, condensation) is a daily, conscious discipline.
- **Steam and caustic mist are constant.** A boiling open tank steams continuously. You're not just splashing it — you're potentially *breathing* it. Ventilation is a primary control.
- **Oxidizers demand respect.** The nitrate/nitrite accelerators are oxidizers — keep them away from fuels, oils, and rags; handle per SDS.
- **The oil/lacquer seal adds fire.** The mandatory finish brings flammability, oil mist, and (if heated) hot-liquid hazards to a line that's already hot.

HEADS-UP — THE BOILING CAUSTIC BATH IS THE DEFINING HAZARD

Burn it into your habits. **Move slowly and deliberately around the black oxide tank.** Lower and raise baskets with the hoist, never by leaning over the bath. Never drop a part in — it displaces boiling caustic upward. **Never add water fast, never dump water in, never let a hose, a drink, a wet glove, or a roof leak put water near this tank.** Keep walkways dry to avoid a slip *toward* the tank. Keep ventilation on. Face shield + caustic/heat gloves + apron, every time. People are hurt on hot lines by *routine* moments — a rushed lift, a wet floor, a careless water top-off — not by dramatic accidents.

REMEMBER

The safety philosophy of this line: **respect the boiling caustic above all; keep water away from the hot bath; control steam and caustic mist; handle the oxidizers like the oxidizers they are; and treat the oil station as a fire hazard.** A black oxide line isn't "the safe line" — it's a line built around a tank that boils hotter than water and burns two ways at once. Give it the discipline it demands and it will never touch you.

PART TWO — THE LINE, STATION BY STATION (STATIONS 01–09)
STATION 01 OF 09

INSPECT & LOAD

“GARBAGE IN, GARBAGE OUT — THE LINE CAN ONLY FINISH WHAT YOU RACK ON IT.”

Before any chemistry touches a part, someone must confirm it's the right part, in the right condition, and load it so the line reaches every surface — and so it **drains** (you never want a part carrying pooled water *toward* the boiling caustic bath). On a black oxide line this is **racking or basketing** for immersion. It feels un-glamorous. It isn't.

• WHAT YOU'RE DOING & WHY IT MATTERS

- **Confirm the job.** Right part number, quantity, spec. Check the traveler for the **substrate** (carbon/alloy steel, cast iron, hardened steel — *not* stainless, copper/brass, zinc, or aluminum), the **finish** (which oil/wax/lacquer seal), the **class/process** (hot/mid/cold), and any spec callout (e.g., MIL-DTL-13924 or AMS 2485).
- **Inspect incoming condition.** Rust, heat-treat scale, weld spatter, heavy oil, or plating from a prior process change the routing (pickle needed? reject?).
- **Load for full contact and full drainage.** Every surface must see solution; every cavity must **drain** so it neither traps soil/acid/caustic nor carries water into the hot bath.

• OPERATOR ESSENTIALS

ITEM	GUIDANCE
Substrate check	Carbon/alloy/cast/hardened steel = this line; stainless, copper/brass, zinc, aluminum = flag, do not run
Class/process	Confirm hot / mid / cold per traveler
Seal finish	Confirm which oil/wax/lacquer the part gets — the seal is mandatory
Orientation	Rack so liquids drain freely — no cups, pockets, or trapped water
Spacing	Parts not touching/nesting — solution must reach all faces
Load weight	Within hoist/basket rating; balanced for safe hot lifts
Pre-clean flags	Heavy oil, rust, scale, weld spatter → route for pickle/special handling

**HEADS-UP**

Mechanical hazards rule this station, and they feed the hot tank. Rack securely so nothing falls into the boiling caustic later (a dropped part erupts hot caustic). **Make sure no part or basket carries pooled water that will dump into the hot bath.** Wear cut-resistant gloves for handling, lift with your legs, use hoists for heavy loads.

• STEP-BY-STEP PROCEDURE

- 1. **Read the traveler.** Confirm part, quantity, substrate, class/process, spec, and the seal finish.
- 2. **Inspect each part** for rust, scale, heavy oil, or damage. Set aside anything needing pickle or rejection.
- 3. **Rack/basket** so every surface is exposed and every cavity drains. Avoid nesting and trapped-water pockets.
- 4. **Confirm spacing, balance, and secure seating** so parts don't shift or fall into the hot bath.
- 5. **Note anything unusual** (wrong substrate, very oily/scaled parts) to your lead before the load enters the line.

• TOP MISTAKES NEW OPERATORS MAKE

- 1. Racking parts that **trap water** in cups/blind holes — eruption hazard at the hot bath.
- 2. **Nesting** parts so faces touch — those faces come out un-blackened.
- 3. Loading the **wrong substrate** (stainless, brass, zinc, aluminum) without flagging it.
- 4. **Overloading or poorly seating** the basket — parts fall into the hot tank.
- 5. Ignoring heavy oil/scale/rust and expecting the cleaner to fix it — it can't.

• TEACH-BACK CHECKLIST

- ☐ Explain why drainage orientation matters (trapped water = eruption risk at the hot bath; trapped solution = contamination).
- ☐ State which substrates this line handles (carbon/alloy/cast/hardened steel) and what to flag (stainless, copper/brass, zinc, aluminum).
- ☐ Identify two mechanical hazards and how they tie to the hot tank.
- ☐ Describe incoming conditions needing a pickle (rust, scale) or rejection.
- ☐ State that the **seal finish is mandatory** and confirm which one the part gets.

SIGN-OFF — STATION 01

Trainee: _____ Trainer: _____ Date: _____

"I confirm I verified the job, substrate, class/process, and seal finish; inspected incoming condition; and racked parts for full contact, free drainage, and safe hot handling with no trapped water, with PPE worn."

STATION 02 OF 09

ALKALINE CLEAN / DEGREASE

“BLACK-OXIDE OVER DIRT AND YOU’VE BLACKENED DIRT.”

This is where oil, grease, coolant, fingerprints, and shop soil come off so the steel is bare and reactive. **Clean steel is non-negotiable:** the magnetite will not grow evenly or black on an oily surface.

• WHAT YOU’RE DOING & WHY IT MATTERS

The cleaner is an **alkaline (high-pH) detergent solution**, usually hot, that **emulsifies and lifts oil/grease, suspends particulate soil, and wets the surface** so nothing redeposits. The result is a uniformly clean, water-loving surface that passes the **water-break test**.

TECHNICAL STUFF

Black oxide cleaners run a range of alkalinity (often pH ~10–13) depending on soil load, sometimes with a soak stage plus a spray or electroclean. Exact concentration and temperature come from the **supplier TDS** — never guess. Note: a black oxide line’s cleaner is often supplied as a matched member of the same chemistry family as the blackening bath; mixing brands can cause compatibility problems.

• OPERATOR ESSENTIALS

PARAMETER	RANGE	NOTES
Temperature	120–180°F	Warmth speeds degreasing; don't exceed TDS max
Time	5–10 min (heavier oil = longer)	—
Concentration	Per supplier TDS (titrate)	Too weak won't cut oil
pH	~10–13 (per product)	—
Agitation	Per equipment	Keeps fresh cleaner on the surface
Oil skimming	Keep surface oil skimmed	Floating oil redeposits on parts

HEADS-UP — HOT ALKALINE SOLUTION

This tank is **hot and caustic**. Splashes cause **chemical burns on contact**; mist irritates airways. PPE every time: splash goggles, face shield (charging/dumping), elbow-length chemical gloves, apron, chemical-resistant boots. First aid: skin → flush 15 min; eyes → eyewash 15 min and get help.

• STEP-BY-STEP PROCEDURE

- 1. **Check the bath** — temperature and concentration in spec (last titration log). Skim surface oil.
- 2. **Inspect the load** — heavy oil → plan for the long end of the time range.
- 3. **Clean fully** — immerse for the full time with agitation; confirm solution reaches all faces.
- 4. **Withdraw and drain** back into the tank.
- 5. **Run the water-break test** on a sample: continuous sheet = pass; beading = fail, re-clean.
- 6. **Move promptly** to the rinse so the clean surface doesn't sit and flash-rust.

TIP — THE WATER-BREAK TEST (FREE, FAST, NEVER LIES)

A clean steel surface loves water and **sheets off in one continuous film**. A dirty surface **beads up**. Continuous sheet = PASS; beading = FAIL (re-clean). Invisible oil is the #1 cause of patchy or brown black oxide.

• TOP MISTAKES NEW OPERATORS MAKE

- 1. **Skipping the water-break test** because the part “looks fine.” The oil that ruins blackening is invisible.
- 2. Running the bath **too cold or too weak** to cut the oil.
- 3. Letting **surface oil build up** with no skimming.
- 4. **Nesting** parts so cleaner can't reach every face.
- 5. Letting clean parts **sit** before rinsing — flash rust and re-soil.

• QUICK TROUBLESHOOTING

SYMPTOM	PROBABLE CAUSE	WHAT TO DO
Water-break fails	Low concentration or temperature	Titrate; bring temp to range
Oily film after cleaning	Floating oil redepositing	Skim; refresh/dump if heavily loaded
Brown/patchy black downstream	Uneven cleaning, trapped air	Reposition load; re-clean

SIGN-OFF — STATION 02

Trainee: _____ Trainer: _____ Conc./Temp: _____

“I confirm parts passed the water-break test, the cleaner was in concentration and temperature range, and I wore required PPE.”

STATION 03 OF 09

RINSE (POST-CLEAN)

“A RINSE ISN’T A REST STOP. IT’S A CHECKPOINT.”

You just got the steel clean — but it’s coated in a film of alkaline cleaner. This station’s job is to **wash that film off** before the part hits the pickle (or, if no pickle, the black oxide bath). Carrying alkaline cleaner into the **acid pickle** neutralizes and contaminates it.

TIP — CONDUCTIVITY

You can’t see dissolved cleaner, so we measure **conductivity** (microsiemens per centimeter, $\mu\text{S}/\text{cm}$) — “the contamination number.” Higher = more cleaner left = dirtier rinse. Lower is cleaner.

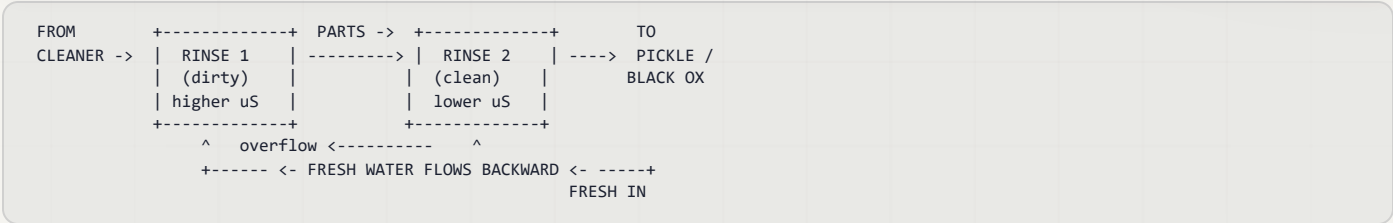

TIP — COUNTER-FLOW RINSING

The professional approach is **counter-current**: parts move forward, fresh water flows backward, so the cleanest water touches the part last. Saves water and rinses better.

• OPERATOR ESSENTIALS

PARAMETER	RANGE	NOTES
Temperature	Ambient (60–85°F)	No heating required
Time	30–60 s with agitation	Longer for blind holes/cavities
Water source	Municipal or DI	DI rinses cleaner, fewer spots
Conductivity	Keep low (e.g. < 500 $\mu\text{S}/\text{cm}$)	Rising = drag-in
Flow	Continuous overflow / counter-current	—

HEADS-UP

Rinse water starts mildly caustic from drag-in. Wear goggles, chemical gloves, and non-slip footwear — the floor here is always wet, and **slips are the #1 injury** (a slip toward the hot caustic tank downstream is especially dangerous).

• **STEP-BY-STEP PROCEDURE**

1. Check conductivity at shift start; rising/high → tell your lead.
2. Confirm water flow (overflow or counter-current active).
3. Transfer promptly from the cleaner — dried cleaner is harder to rinse.
4. Rinse fully, 30–60 s, with agitation; flush blind holes longer.
5. Drain briefly, then move promptly to the next stage.

• **TOP MISTAKES NEW OPERATORS MAKE**

1. Treating the rinse as “quick” — a two-second dunk rinses nothing.
2. Ignoring conductivity — a high number means you’re carrying cleaner into the pickle right now.
3. Letting the part drip-dry between stages — dried cleaner is stubborn.
4. Not flushing blind holes/tubes — concentrated cleaner hides and rides forward.

• **TEACH-BACK CHECKLIST**

- ☐ Explain why carrying cleaner forward hurts the pickle (and the black oxide bath).
- ☐ Define drag-out / drag-in.
- ☐ Explain what conductivity tells you (lower = cleaner).
- ☐ State the rinse time and why cavities need longer.

SIGN-OFF — STATION 03

Trainee: _____ Trainer: _____ Conductivity: _____ $\mu\text{S}/\text{cm}$

“I confirm rinse conductivity was within limit, water flow was running, and parts were rinsed the full time with PPE worn.”

STATION 04 OF 09 • AS NEEDED

ACID PICKLE / DESCALE

“YOU CAN’T BLACK-OXIDE RUST OR SCALE — STRIP IT TO BRIGHT STEEL FIRST.”

Black oxide grows on **clean, bare, oxide-free steel**. If parts arrive rusty, scaled, or carrying heat-treat oxide, the alkaline cleaner won’t remove that. An **acid pickle** strips rust and scale down to bright, reactive steel. On clean, already-bright stock, this step (and its rinse, Station 05) is skipped — confirm with your lead and the spec.

• WHAT YOU’RE DOING & WHY IT MATTERS

A dilute mineral acid (typically **hydrochloric or sulfuric**, per the supplier TDS) dissolves rust and scale. Sometimes a mild acid **activation** dip is used even on clean parts to remove the last invisible oxide film and leave a uniformly reactive surface for an even black.

• OPERATOR ESSENTIALS

PARAMETER	RANGE	NOTES
Acid / strength	Per supplier TDS	Never guess concentration
Temperature	Ambient-warm (per TDS)	—
Time	Just enough to strip rust/scale	Over-pickling roughens steel & risks embrittlement
Inhibitor	Per TDS (often inhibited)	Reduces base-metal attack & hydrogen

**HEADS-UP**

The pickle is **acid** — corrosive to skin/eyes/lungs; can generate hydrogen and fumes. Full acid PPE. **Acid and the downstream caustic bath are chemical opposites — never let them mix in bulk**; that’s why Station 05 (rinse) sits between them.

**TECHNICAL STUFF**

Aggressive pickling of high-strength/hardened steels risks **hydrogen embrittlement**. Follow the spec’s pickling limits and any required **post-bake** for hydrogen relief. This is a structural-safety issue — escalate to your chemist/engineer when in doubt.

• **STEP-BY-STEP PROCEDURE**

- 1. Confirm the part actually needs pickling (rust/scale present) per traveler/spec.
- 2. Check acid strength and temperature against the TDS.
- 3. Immerse just long enough to strip rust/scale to bright steel — no longer.
- 4. Withdraw, drain, and move straight to the post-pickle rinse.

• **TOP MISTAKES NEW OPERATORS MAKE**

- 1. **Over-pickling** — roughened surface, embrittlement risk.
- 2. **Skipping the pickle** on rusty/scaled parts → brown, patchy black oxide.
- 3. **Dragging acid toward the caustic bath** without rinsing.
- 4. Pickling high-strength parts without checking the embrittlement/bake requirement.

• **TEACH-BACK CHECKLIST**

- ☐ State when the pickle is run and when it's skipped (rusty/scaled vs. bright stock).
- ☐ Explain why acid must never reach the caustic bath in bulk.
- ☐ Describe the over-pickling and hydrogen-embrittlement risks.
- ☐ Name the acid PPE required at this station.

SIGN-OFF — STATION 04

Trainee: _____ Trainer: _____ Acid/Strength: _____

"I confirm the parts required pickling, acid strength/temperature were in range, parts were pickled to bright steel without over-pickling, and embrittlement requirements were checked, with PPE worn."

STATION 05 OF 09

RINSE (POST-PICKLE)

“DON’T CARRY ACID INTO A TANK OF BOILING CAUSTIC.”

A pickled part is wet with acid. This rinse removes that acid before the part enters the black oxide bath. Dragging acid into the caustic bath neutralizes/contaminates it and adds an unwanted heat-releasing reaction in the most dangerous tank on the line.

• OPERATOR ESSENTIALS

PARAMETER	RANGE	NOTES
Temperature	Ambient	—
Time	30-60 s with agitation	Flush cavities longer
Flow	Continuous overflow / counter-current	—
pH	Near neutral after rinse	Acidic rinse = acid drag-in

HEADS-UP

Same slip/caustic-proximity rules as the other rinses, plus **acid drag-in** — keep this rinse flowing and don’t let it turn acidic, or you defeat its purpose and start carrying acid toward the caustic bath.

REMEMBER

“Drag acid into caustic and you wound the black oxide bath.” This rinse and the post-clean rinse are the firewalls on either side of the pickle. Don’t skimp on either.

• STEP-BY-STEP PROCEDURE

1. Confirm water flow.
2. Transfer promptly from the pickle.
3. Rinse fully, flush cavities.
4. Drain briefly, then move to the black oxide bath.

• TEACH-BACK CHECKLIST

- ☐ Explain why acid must not reach the boiling caustic bath.
- ☐ State why an acidic rinse defeats the firewall.
- ☐ Describe the slip hazard near the downstream hot tank.

SIGN-OFF — STATION 05

Trainee: _____ Trainer: _____ Date: _____

“I confirm parts were rinsed free of acid before the black oxide bath, water flow was running, with PPE worn.”

STATION 06 OF 09 • THE MAIN EVENT

BLACK OXIDE — THE MAIN EVENT

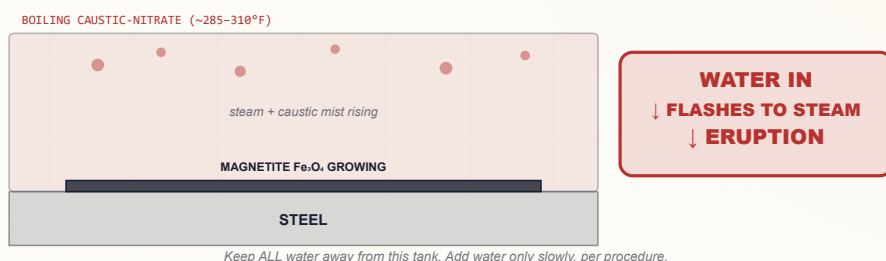

“THIS IS THE BOILING CAUSTIC TANK. EVERYTHING YOU’VE LEARNED ABOUT SAFETY LIVES HERE.”

Now — with a clean, bare, oxide-free, well-rinsed steel surface — the conversion coating actually forms, in the **boiling caustic-nitrate bath**. The hot caustic attacks the iron; the nitrate/nitrite oxidizers control its oxidation; black **magnetite (Fe_3O_4)** grows into the surface. This is the payoff stage — and by far the most dangerous one. Read every word of this chapter twice.

• WHAT YOU’RE DOING & WHY IT MATTERS

The bath is **concentrated sodium hydroxide with nitrate/nitrite oxidizers**, boiling at **~285–310°F**. The part is immersed (slowly, with a hoist) for several minutes until the magnetite has fully grown to an even, deep black. The bath’s high salt concentration is *why* it boils far above water’s 212°F — and *why* water entering it flashes to steam.

THE HOT BATH — AND ITS SIGNATURE DANGER

HEADS-UP — THE STANDOUT HAZARD ON THE ENTIRE LINE

The bath is **boiling concentrated caustic at ~285–310°F — hotter than boiling water**. It burns **chemically and thermally** at the same time. A splash, a dropped part, or leaning over the tank causes **severe instant burns**. And the unique killer: **water in ANY form — a dump, a wet part, a dripping hose, condensation, a roof leak — flashes to steam on contact and can ERUPT boiling caustic out of the tank onto everyone nearby**. Lower/lift parts **slowly** with the hoist; never drop a part in; make sure parts/baskets carry no pooled water; **NEVER add water fast or dump water in**; keep all stray water away; keep your face and body back; run the ventilation; wear face shield + caustic/heat gloves + apron.

• OPERATOR ESSENTIALS

PARAMETER	RANGE	NOTES
Temperature	~285–310°F (141–154°C)	Hotter than boiling water; set by concentration
Time / dwell	~5–20 min	Until full, even black; per TDS/part
Concentration	Per supplier TDS	Controls boiling point & color; too low/high → smut/haze
Oxidizer level	Per TDS	Low oxidizer → red/brown smut instead of black
Iron / carbonate	Monitor & control	High iron/carbonate → brown smut, rub-off, poor black
Water additions	Slow, careful, per procedure	The signature hazard — see below

HEADS-UP — CONTROLLED WATER ADDITIONS

Yes, you *do* add water to this bath — to replace what boils off and keep the temperature/concentration in range. But this is the single most dangerous routine task on the line. Add water **only per written procedure**: slowly, in small amounts, with the bath under control, with the operator clear of the splash zone and in full PPE. **Never a fast pour, never a hose left running, never an unattended addition.** When in doubt, get your lead. This is exactly the moment the “water flashes to steam” lesson saves someone.

HEADS-UP — CAUSTIC MIST & OXIDIZERS

The boiling bath throws **caustic mist** (run local exhaust; don’t breathe it). The **nitrate/nitrite oxidizers** must be kept away from fuels, oils, and rags. Never combine chemistries or make additions you’re not trained and authorized for.

REMEMBER

Concentration and temperature are **linked** — you can’t chase one without watching the other. As water boils off, concentration rises and the boiling point climbs; controlled water additions bring both back into range. That is the daily rhythm of running this tank safely.

• STEP-BY-STEP PROCEDURE

1. **Confirm the bath is in range** — temperature, concentration, oxidizer, iron/carbonate per the log/TDS. If it's out of range, do not run; tell your lead.
2. **Confirm parts carry no pooled water** and are racked to drain.
3. **Lower the basket SLOWLY with the hoist** — never drop it in; stand clear of the surface.
4. **Dwell** the required time until a full, even, deep black has grown.
5. **Raise SLOWLY**, let it drain over the tank, and move to the post-black-oxide rinse promptly (don't let caustic dry on the part).
6. **Make water/chemistry additions only per procedure**, slowly and clear of the splash zone.

• READING THE COATING (AT THE BATH)

- **Good:** uniform, deep, even black; full coverage; no bare/brown spots.
- **Red haze / brown smut:** reddish or brown film/powder — usually **low concentration, exhausted/old bath, low oxidizer, high iron/carbonate, poor cleaning, or too-short dwell**. Tells you the bath grew the *wrong* iron oxide. Rinse, check bath chemistry, re-run.
- **Gray/patchy/thin:** poor cleaning, missed pickle, weak or too-cool bath.
- **Powdery rub-off:** bath imbalance/contamination (high iron/carbonate).

TIP

A correct part comes out of the bath an even, deep, uniform black before it ever sees oil. If you see reddish or brown tones at the tank, don't "oil over" the problem — the oil can't fix a bad coating, it only deepens a good one. Rinse, check the bath, and re-run.

REMEMBER

You read black oxide by **uniform deep black, full coverage, and the absence of red/brown smut** — not by iridescence. Red haze means the bath grew the wrong oxide; that's a bath-chemistry message, not a cosmetic one.

• TOP MISTAKES NEW OPERATORS MAKE

1. **Dropping a part in** (splash/displacement) or **leaning over the tank**.
2. **Letting any water near the tank** — wet part, hose, drink, dumped water → eruption.
3. **Adding water fast** instead of slow/controlled per procedure.
4. **Running an out-of-range bath** (low concentration/oxidizer, high iron) → red haze/brown smut.
5. **Letting caustic dry on the part** instead of rinsing promptly → residue and corrosion.

• TEACH-BACK CHECKLIST

- ☐ Explain **why** the bath boils above 212°F (concentrated caustic) and why that makes water flash to steam.
- ☐ State the temperature range and the worst hazards (scald + chemical burn + eruption).
- ☐ Describe the **safe water-addition rule** (slow, small, per procedure, clear of splash zone).
- ☐ Explain red haze / brown smut and its likely causes.
- ☐ State the full PPE required at this tank.

DO

- Lower/raise baskets slowly with the hoist.
- Keep face and body back; run ventilation.
- Add water only slowly, per procedure, clear of splash.
- Verify the bath is in range before running.

NEVER

- Drop a part in or lean over the tank.
- Dump water in or leave a hose running nearby.
- Lower a part carrying pooled water.
- Combine chemistries or make unauthorized additions.

• BATH DEFECTS AT A GLANCE

WHAT YOU SEE	PROBABLE CAUSE	WHAT TO DO
Uniform deep black, full coverage	Clean steel, balanced bath	Rinse & seal — good
Red haze / reddish film	Low concentration/oxidizer, exhausted bath, short dwell	Check & adjust bath; extend dwell; re-run
Brown smut / powder	High dissolved iron or carbonate; imbalance	Bath analysis; decant/replace per program
Gray / thin / patchy	Poor cleaning, missed pickle, weak/cool bath	Re-clean; pickle if scaled; verify bath
Powdery rub-off	Bath contamination (iron/carbonate)	Bath control; decant/replace

REMEMBER

The black oxide tank is where everything upstream pays off and where the line's worst hazard lives. Run it with discipline: **verify the bath, handle slowly with the hoist, keep water away, control the mist, and never improvise.** A part that comes out an even, deep black from a well-controlled bath is the whole point of the line.

HEADS-UP

If you ever see the bath **surge, spit, or “crackle” oddly — back away and get your lead.** That can be water finding its way in. Do not approach until it settles and a lead clears it.

SIGN-OFF — STATION 06

Trainee: _____ Trainer: _____ Bath Temp/Conc.: _____

“I confirm I verified the bath was in range, lowered/raised parts slowly with the hoist (no drops, no leaning), kept all water away from the tank, made any water additions only per procedure and clear of the splash zone, ran ventilation, and wore full PPE including a face shield.”

STATION 07 OF 09

RINSE (POST-BLACK-OXIDE)

“GET EVERY TRACE OF CAUSTIC OFF — FOR THE PART’S SAKE AND THE NEXT PERSON’S HANDS.”

The part leaves the bath coated in clinging hot caustic. This station removes it — commonly a **cold-water rinse followed by a hot-water rinse**. Leftover caustic causes white residue, blotchy color, and corrosion under the oil later — and is a contact hazard for whoever handles the “finished” part. The hot final rinse also warms the part so it flash-dries and accepts oil better.

• OPERATOR ESSENTIALS

PARAMETER	RANGE	NOTES
Cold rinse	Ambient, flowing	Knocks down the bulk of the caustic
Hot rinse	~160–200°F	Removes last caustic; warms part for oiling
Time	~1–2 min total, agitated	Flush cavities longer
Flow	Continuous overflow / counter-current	—

**HEADS-UP**

This rinse water carries dragged-out **caustic** and the first rinse is **hot**. Goggles, gloves, apron, non-slip boots. Don't let caustic dry on parts between the bath and the rinse.

**REMEMBER**

Caustic residue under the oil is a future corrosion spot — and a hazard to bare hands downstream. Rinse thoroughly; this is the wall between the boiling-caustic bath and the seal.

• STEP-BY-STEP PROCEDURE

1. Move promptly from the black oxide bath (don't let caustic dry).
2. Cold rinse with agitation; flush cavities.
3. Hot rinse to remove the last caustic and warm the part.
4. Drain; move directly to the oil/seal step while the part is warm.

SIGN-OFF — STATION 07

Trainee: _____ Trainer: _____ Date: _____

“I confirm parts were rinsed free of caustic (cold then hot), no caustic was allowed to dry on the part, and PPE was worn.”

STATION 08 OF 09 • MANDATORY FINISH

OIL / WAX / LACQUER SEAL

“THE OXIDE IS THE CARRIER. THE SEAL IS THE PROTECTION. NEVER SKIP IT.”

This is **not optional**, and there is **no alternative route**. Bare black oxide gives only minimal corrosion resistance — left unsealed it rusts fast. The **oil, wax, or lacquer** penetrates the porous magnetite, seals it, **provides the corrosion protection**, and **deepens the black** to its final rich appearance.

• WHAT YOU’RE DOING & WHY IT MATTERS

You dip or apply a sealing medium to the warm, clean black-oxidized part. The warmth and the porosity draw the seal into the magnetite and displace any trace water. Common choices:

- **Water-displacing / preservative oil** — most common; good handling and indoor protection; deep black.
- **Heavier oil or wax** — better/longer corrosion protection; less oily feel (wax).
- **Lacquer / topcoat** — a dry, durable, fingerprint-resistant black for parts that shouldn’t feel oily.

• OPERATOR ESSENTIALS

PARAMETER	RANGE	NOTES
Seal medium	Per traveler/TDS	Oil vs wax vs lacquer sets performance & feel
Temperature	Ambient to hot (per product)	Warm part + warm oil = best penetration
Time	1–10 min (per product)	Long enough to fully penetrate the pores
Drain/cure	Per product	Drain excess; let oil set / lacquer cure

★

REMEMBER
The seal is mandatory and central — never skipped. “Black oxide + seal” is the actual product. The medium you pick *is* the corrosion-protection decision: thin oil for indoor/handling, heavier oil/wax for tougher service, lacquer for a dry durable black. Match it to the part’s job and the spec.

⚠

HEADS-UP
The seal station adds **oil-mist, flammability, and (if hot) hot-oil/solvent** hazards (lacquers add **solvent vapor**). Keep ignition sources away, control mist/vapor with ventilation, follow the product TDS for temperature, and **never plunge a dripping-wet part into a hot-oil tank** — trapped water flashes to steam there too.

• STEP-BY-STEP PROCEDURE

- 1. Confirm the correct seal medium and its temperature per the traveler/TDS.
- 2. Seal the warm part — immerse/apply for the full time so the pores fill.
- 3. Withdraw and **drain excess** back to the tank.
- 4. Let the film **set / cure** before handling or boxing.

• TOP MISTAKES NEW OPERATORS MAKE

- 1. **Skipping or rushing the seal** — the part rusts within hours.
- 2. **Sealing a part with trapped water** (not warmed/dried) — rust under the film.
- 3. **Wrong medium** for the part's service (thin oil where wax/lacquer was specified).
- 4. **Boxing before the film sets** — smears, drips, fingerprints.

• TEACH-BACK CHECKLIST

- ☐ Explain **why** the seal is mandatory and what it actually does (corrosion protection + deeper black).
- ☐ State the three seal families and when each is used.
- ☐ Explain why trapped water under the seal causes rust.
- ☐ Identify the fire/mist/solvent hazards of this station.

TIP

Seal the part *while it's still warm* from the hot rinse. A warm part and warm oil pull the seal deep into the pores and drive off the last trace of water — the difference between a part that sheds water for months and one that spots in a week.

SIGN-OFF — STATION 08

Trainee: _____ Trainer: _____ Seal medium: _____

"I confirm the correct seal medium was applied to a clean, water-free part, the pores were sealed and excess drained, the film was allowed to set, and fire/mist controls and PPE were observed."

STATION 09 OF 09 • THE FINISH LINE

INSPECT & HAND-OFF

“LAST CHANCE BEFORE THE CUSTOMER.”

A final look confirms the coating is a uniform, deep, even **black** with **full coverage**, **no red haze or brown smut**, **minimal rub-off**, and a properly **sealed** surface — then it ships or moves to assembly.

• WHAT GOOD VS. BAD LOOKS LIKE

WHAT YOU SEE	ROUGHLY WHAT IT MEANS	VERDICT
Uniform deep black, full coverage, sealed, sheds water	Clean steel, balanced bath, good seal	Good
Red/reddish haze or brown smut	Old/low/low-oxidizer bath, high iron/carbonate, poor clean, short dwell	Bad — check bath & cleaning
Gray, thin, patchy, bare spots	Poor cleaning, missed pickle, weak/cool bath	Bad — reprocess upstream
Powdery layer that rubs off	Bath imbalance/contamination (iron/carbonate)	Bad — bath control
Black but rusts/spots soon after	Seal skipped/poor, or caustic/water trapped	Bad — seal & post-rinse

REMEMBER

You read black oxide by **color uniformity**, **full coverage**, **absence of red/brown smut**, **rub-off**, and a **properly sealed (water-shedding) surface** — *not* by iridescence. A good part is an even, deep, uniform black, sealed, with no bare or brown spots and no loose powder.

• STEP-BY-STEP PROCEDURE

1. Inspect color, coverage, and uniformity in good light.
2. Check for red haze / brown smut / gray patches.
3. Do a light **rub-off check** — excessive powder is a reject.
4. Confirm the part is **sealed** (oiled/waxed/lacquered) and water-free.
5. Confirm no mechanical damage; package per spec.

SIGN-OFF — STATION 09

Trainee: _____ Trainer: _____ Date: _____

“I confirm the coating was uniform deep black with full coverage, no red haze/brown smut, acceptable rub-off, properly sealed, and undamaged before hand-off.”

PART THREE — ACROSS THE LINE
HOT VS. MID VS. COLD

THE THREE TEMPERATURE CLASSES COMPARED

SAME GOAL — A BLACK SURFACE — THREE VERY DIFFERENT CHEMISTRIES, PERFORMANCES, AND HAZARDS

	HOT	MID-TEMPERATURE	COLD / ROOM-TEMP
Temp	285–310°F	~200–250°F	~ambient
Chemistry	Caustic + nitrate/nitrite	Alkaline oxidizing (less caustic)	Selenium-based (selenious acid + copper)
Coating	True magnetite Fe ₃ O ₄	True magnetite Fe ₃ O ₄	Selenide film (NOT magnetite)
Best for	Highest quality / spec work	Lower-fume hot alternative	Touch-up, repair, low-demand
Durability/abrasion	Best	Good	Lowest
Corrosion (oiled)	Best	Good	Lowest
Standout hazard	Boiling caustic + water-flash eruption	Hot/caustic (less fuming)	Selenium toxicity / waste
Seal required?	Yes	Yes	Yes

★

REMEMBER

Hot is the standard and the benchmark; mid trades a little performance for less fuming and a lower (still hot) temperature; cold trades real durability for speed, safety, and convenience — and is chemically a *different coating* (selenide, not magnetite). All three need the oil seal.

⚙

TECHNICAL STUFF

Because the cold process is a selenium-based displacement film rather than grown iron oxide, it behaves differently in service: thinner, softer, and quicker to wear or corrode through. It earns its place for field touch-up and low-demand work, but specifying it where a hot magnetite finish is required is a quality (and sometimes audit) failure. Match the class to the spec.

💡

FUN FACT

All three processes end at the same place — an oil bath. No matter how the black got there, the corrosion protection always comes from the seal. The oil doesn't care whether it's sealing magnetite or a selenide film; it just fills pores and sheds water.

— THE CHAPTER THAT KEEPS YOU ALIVE

HOT-BATH OPERATION & THE STEAM-ERUPTION HAZARD

READ IT EVEN IF YOU SKIP EVERY OTHER PART THREE SECTION

• WHY IT BOILS SO HOT

Dissolving a large amount of sodium hydroxide raises water's boiling point. A correctly concentrated hot black oxide bath boils at **~285–310°F**. As water evaporates through the day, the bath gets more concentrated and the boiling point *climbs*. You control it by **carefully adding water** to restore level/concentration and bring the temperature back into range.

• WHY THAT'S THE HAZARD

Because the bath sits **far above water's 212°F boiling point**, any water that contacts it **instantly flashes to steam**. Steam expands violently — and the expansion **erupts boiling caustic up and out of the tank**. This is the signature danger of a black oxide line and the cause of its worst injuries.

HEADS-UP — THE RULES THAT PREVENT AN ERUPTION

- **NEVER** add water quickly or dump water into a hot caustic bath. Additions are slow, small, controlled, per written procedure, with the operator clear of the splash zone.
- **Keep water away from the tank** — no hoses left running nearby, no open drinks, no leaks/condensation dripping in, no wet mops over the tank.
- **Make sure parts and baskets carry no pooled water** into the bath.
- **Lower/raise parts slowly with a hoist** — never drop them in (displacement throws solution).
- **If you ever see the bath surge, spit, or “crackle” oddly, back away and get your lead** — that can be water finding its way in.

REMEMBER

Water is your friend on your *skin* (flush a splash for 15+ minutes) and your enemy in the *bath* (eruption). That contradiction is the heart of black oxide safety. Internalize it.

• BATH CONTROL: IRON AND CARBONATE

Two routine control jobs ride alongside water control. **Iron** dissolved from the parts and **carbonate** (from caustic absorbing carbon dioxide over time) both accumulate in the bath. When they get high, they push the bath toward **brown smut, red haze, rub-off, and dull/incomplete black**.

CONTROL ITEM	WHAT HAPPENS IF IT DRIFTS	HOW IT'S MANAGED
Concentration / boiling point	Too low: weak/red coating. Too high: overheated, fuming	Controlled water additions per procedure
Oxidizer (nitrate/nitrite)	Low: red/brown smut instead of black	Replenish per supplier program
Dissolved iron	High: brown smut, rub-off, poor black	Decant/partial replacement per program
Carbonate	High: dull, incomplete, hazy black	Scheduled bath maintenance/replacement

**TECHNICAL STUFF**

Bath analysis on a schedule, plus periodic decanting/replacement per the supplier program, keeps the bath growing clean magnetite. Concentration and temperature are linked — you can't chase one without watching the other — so bath logs track both together, along with oxidizer, iron, and carbonate. A black oxide bath is a living system that drifts as it works; the log is how you stay ahead of it.

**TIP**

When good parts suddenly start coming out brown or hazy and cleaning checks out, suspect the bath: rising iron or carbonate, or falling oxidizer. That's a “tell your lead and check the log” moment, not a “run it longer” moment.

**HEADS-UP**

Bath additions and maintenance — caustic, oxidizer, water, decanting — are done **only by trained, authorized personnel, in full PPE, with ventilation running, and per written procedure**. The water-addition rule applies to every one of these tasks: slow, small, clear of the splash zone.

THE STEP THAT DOES THE PROTECTING

OIL / WAX / LACQUER SEALING — WHY IT’S MANDATORY

THE MAGNETITE IS THE CARRIER; THE SEAL IS THE CORROSION PROTECTION

The magnetite layer is thin and **porous**. Bare, it offers only minimal corrosion resistance — it will rust. The seal does three things: **fills the pores, provides the corrosion protection, and deepens/enriches the black**. Choosing the medium *is* choosing the protection level:

- **Water-displacing / preservative oil** — most common; good indoor/handling protection; deep black; oily feel.
- **Wax** — better, longer protection; drier feel; good for parts that can’t be oily-wet.
- **Lacquer / dry-film topcoat** — durable, fingerprint-resistant, dry black; for parts that must not feel oily and need extra durability.

SEAL MEDIUM	PROTECTION	FEEL	TYPICAL USE
Preservative oil	Good (indoor/handling)	Oily	General tools, fasteners, hardware
Wax	Better / longer	Dry-ish	Parts that can’t stay oily-wet
Lacquer / topcoat	Durable, dry barrier	Dry, hard	Display, fingerprint-sensitive, durable black

★

REMEMBER

“Black oxide” without a seal is an unfinished part. The spec language reflects this — military and aerospace standards define black oxide **with a supplementary oil/preservative** (see specs, next pages). Always confirm which seal the spec/customer requires.

⚠

HEADS-UP

Hot-oil and lacquer sealing add **flammability, oil/solvent mist, and hot-liquid** hazards. Keep ignition sources away, ventilate, follow the product TDS, and never seal a dripping-wet part in a hot-oil tank — trapped water flashes to steam there too.

— BLACK OXIDE’S QUIET SUPERPOWER

DIMENSIONAL NEUTRALITY

THE REASON PRECISION PARTS GET BLACKED INSTEAD OF PLATED

Because magnetite is only ~0.5–2.5 µm and grows partly *into* the steel, the net size change is tiny — often well under a ten-thousandth of an inch per surface. For most parts you cannot measure a meaningful change.

★

REMEMBER

This is *the* reason precision parts get black-oxidized instead of plated. A plated part **grows** by the plating thickness (microns to tens of microns), which can throw threads, bores, gears, and gauges out of tolerance. A **black-oxidized part stays essentially the same size**. When the customer needs black + corrosion + tight tolerances, black oxide wins.

FINISH	TYPICAL BUILD PER SURFACE	EFFECT ON TIGHT TOLERANCES
Black oxide	~0.5–2.5 µm (grows partly in)	Essentially none — part stays in spec
Zinc plating	~5–25 µm	Can bind threads, shrink bores
Phosphate (zinc/mn)	measurable coating weight	Adds measurable build

💡

FUN FACT

Gauge blocks, precision gears, and fine-threaded fasteners are often blacked precisely because the finish doesn’t change the fit. You can black-oxide a go/no-go gauge and it still gauges.

💡

TIP

When a customer wants a black, corrosion-resisting finish on a threaded or close-tolerance steel part and is worried about fit, black oxide is usually the right answer — it blacks the part without measurably changing its size. (Confirm the corrosion requirement is modest enough for an oil-sealed finish.)

— WHERE BLACK OXIDE FITS

DECORATIVE & ANTI-GLARE USES

BLACK, NON-REFLECTIVE, DIMENSIONALLY NEUTRAL — AND HONEST ABOUT WHERE IT DOESN'T BELONG

• WHERE BLACK OXIDE FITS

- **Decorative black** — uniform, attractive matte-to-satin black across mixed steel hardware.
- **Anti-glare / non-reflective** — black oxide kills reflections, which is why it's standard on **optical and sighting parts**, camera/scope internals, and tooling where glints are unwanted.
- **Mild corrosion + handling protection** — when sealed; good for indoor, enclosed, or oiled-service parts.
- **Dimensional neutrality** — for tight-tolerance parts (gears, gauges, fine threads).

• WHERE IT DOES NOT FIT

- **Harsh outdoor/marine corrosion service** — use zinc plating or heavy zinc phosphate instead.
- **As a paint base** — use a phosphate pretreatment instead.

Black oxide is decorative / anti-glare / mild-corrosion / dimensionally-neutral — **not** a heavy corrosion barrier and **not** a paint primer.

FUN FACT — BLUING VS. BLACK OXIDE

Firearms people often use “bluing” and “black oxide” interchangeably, but they're related cousins, not twins. Classic **bluing** is a controlled rusting/oxidizing finish (often hot-caustic-nitrate, like black oxide's hot bath) that produces a blue-black oxide on steel; **black oxide** is the broader industrial family of the same idea. Both grow an iron-oxide film and both **live or die by the oil** that seals them.

REMEMBER

Pick black oxide for **black + glare-control + tight tolerances + mild (oiled) corrosion resistance**. Reach for zinc/phosphate or plating when the job is heavy corrosion service or a paint base. Right finish for the right job.

WHAT THE TRAVELER CALLS OUT

SPECS : THE ONES YOU’LL SEE

READ THE CLASS OFF THE DRAWING — NEVER QUOTE IT FROM MEMORY

SPEC	WHAT IT IS
MIL-DTL-13924	“Coating, Oxide, Black, for Ferrous Metals” — the principal U.S. military spec for black oxide on steel/ferrous parts. It defines several classes that correspond to substrate type and process (different temperature/alkaline processes for plain carbon/low-alloy steels, stainless, and hardened/precipitation-hardened steels).
AMS 2485	The aerospace (SAE) black oxide spec for ferrous parts.
ASTM D769	A historical ASTM specification for black oxide coatings on iron and steel (older reference; verify current status before citing).

**HEADS-UP — DON’T QUOTE CLASS NUMBERS FROM MEMORY**

We are not going to give you exact MIL-DTL-13924 class definitions or numbered breakpoints here, because getting a spec class wrong on a traveler can scrap a job or fail an audit. **Always read the class/type/grade requirement off the customer’s drawing and confirm it against the current revision of the actual spec** (the supplier TDS and your QC department have controlled copies). When a traveler says “MIL-DTL-13924 Class __,” verify what that class requires — don’t assume.

**REMEMBER**

All of these specs describe black oxide **with its supplementary oil/preservative** — the seal is part of the spec, not an extra. Confirm both the coating class *and* the required seal with QC.

**TECHNICAL STUFF**

Because ASTM D769 is an older/historical reference, the shop should confirm its current status before printing it on a customer-facing traveler. CAS numbers and exact class breakpoints are deliberately left to your controlled documents — publish nothing you can’t verify against a current source.

— STEEL ONLY — KNOW THE EXCEPTIONS

BLACK OXIDE ON OTHER METALS

STAINLESS, COPPER/BRASS, AND ZINC EACH NEED A DIFFERENT CHEMISTRY

Classic black oxide — this manual — is a **steel/iron** process. Other metals get *different* chemistries:

- **Stainless steel** — blackened by a **different alkaline oxidizing process** (typically a different, often higher-temperature caustic chemistry); not the same bath as carbon steel.
- **Copper and brass** — blackened by **different chemistries** (sulfide/selenide or proprietary blackeners) — not iron-oxide chemistry at all.
- **Zinc and zinc-plated parts** — blackened by their own **separate processes**; the carbon-steel caustic bath would attack zinc.

METAL	THIS CARBON-STEEL LINE?	CORRECT ROUTE
Carbon / alloy / cast / hardened steel	Yes	This black oxide line
Stainless steel	No	Different (often higher-temp) caustic process
Copper / brass	No	Different blackener (sulfide/selenide/proprietary)
Zinc / zinc-plated	No — bath attacks zinc	Separate zinc blackening process
Aluminum	No	Anodize / different finish

★

REMEMBER
If a stainless, copper/brass, or zinc part shows up on the steel black oxide line, **flag it — do not run it**. Wrong metal, wrong bath, ruined part (and the caustic bath attacks zinc). This manual = carbon/alloy/cast/hardened **steel** only.

💡

TIP
A magnet won't tell you everything, but it's a quick first screen: most carbon and alloy steels are magnetic; austenitic stainless, copper, brass, and aluminum are not. If a "steel" part doesn't grab a magnet, stop and confirm the substrate before it reaches the caustic tank.

— CAUSTIC + NITRATE + SELENIUM + OIL

WATER, RINSE & WASTE

SEVERAL REGULATED STREAMS — AND REAL LEGAL OBLIGATIONS

A black oxide line produces several regulated waste streams:

- **Spent caustic** — very high pH; must be **neutralized** and handled per your permit. Never pour caustic to drain.
- **Nitrate / nitrite** — the oxidizers are regulated in wastewater (nitrogen) and are oxidizing-hazard chemicals in storage.
- **Iron/carbonate sludge** — from bath decanting/maintenance.
- **Selenium (cold process only)** — selenium is **toxic and tightly regulated** (a listed/characteristic hazardous-waste concern). Cold-blackening waste needs special handling.
- **Oily waste** — spent seal oils/waxes and oily rinse from the seal step.

HEADS-UP

Never mix the acid pickle waste and the caustic waste in bulk uncontrolled — that's a violent, heat-releasing reaction. Segregate, neutralize, and dispose per your shop's permitted procedure. Keep oxidizers away from oils/fuels/rags in storage.

REMEMBER

Drag-out control (rinsing, drip trays) cuts both your chemical cost *and* your waste load. Good rinsing isn't just quality — it's environmental compliance.

TECHNICAL STUFF

Never dump any bath, rinse, or skimmed oil down a drain on your own judgment. Discharges are permitted and treated — caustic neutralized, nitrate/nitrite managed for nitrogen, selenium handled as the toxic/regulated waste it is, and oily streams collected separately. Follow your shop's waste procedures and your wastewater permit; violations carry serious legal and environmental consequences.

— HOW WE PROVE IT WORKED

QUALITY CHECKS

BLACK OXIDE IS JUDGED WITH THE OIL ON — NEVER ON THE BARE OXIDE

CHECK	HOW	WHAT IT TELLS YOU
Water-break (pre-coat)	Watch water sheet vs. bead on cleaned part	Clean (sheet) vs. oily (bead) — gates the whole job
Color & coverage	Visual, good light	Uniform deep black, full coverage = good; gray/patchy/brown = problem
Red haze / brown smut	Visual	Bath chemistry/age, iron/carbonate, cleaning, or dwell issue
Rub-off (smut) test	Wipe with clean cloth	Light smut may be normal pre-seal; heavy powder = reject (bath imbalance)
Seal verification	Confirm oiled/waxed/lacquered; water sheds	Unsealed = will rust
Salt-spray / corrosion — WITH oil	Per spec, on the sealed part	The real corrosion performance — always tested with the seal on
Adhesion / appearance	Per spec	No flaking, even sheen

★

REMEMBER
Corrosion testing on black oxide is done **WITH the oil/seal applied** — never on the bare oxide. Bare magnetite fails a salt-spray test almost immediately; that’s expected and not a defect. The corrosion spec describes “black oxide + seal,” so that’s what you test.

⚙️

TECHNICAL STUFF — WHAT IS “SALT SPRAY”?
It’s an accelerated corrosion test (per ASTM B117): sealed samples sit in a sealed cabinet sprayed with salt fog, and you record how many *hours* until rust/spots appear. More hours = better protection. For black oxide it is always run on the **oiled** part, because the oil-sealed coating is the product the spec describes.

💡

TIP
The fastest in-process predictor of a good part is the trio you can do at the tank: **water-break (clean), uniform deep black (good bath), light rub-off (balanced bath)**. Get those three and the seal, and the salt-spray result almost always follows.

FIELD REFERENCE

TROUBLESHOOTING QUICK-INDEX

FIND YOUR SYMPTOM, READ THE LIKELY CAUSE, TRY THE FIX

SYMPTOM	PROBABLE CAUSE	WHAT TO DO
Red haze / reddish film	Low concentration, low oxidizer, exhausted/old bath, too-short dwell	Check & adjust bath chemistry; extend dwell; rinse well; re-run
Brown smut / powder	High dissolved iron or carbonate; bath imbalance; poor rinsing	Bath analysis; decant/replace per program; improve post-rinse
Gray / thin / patchy black	Poor cleaning, missed pickle, weak or too-cool bath	Re-clean; pickle if scaled; verify bath temp/conc.; reprocess
Bare spots	Oil/soil not removed; nested parts; trapped air	Re-clean (water-break); re-rack for full contact
Coating rubs off (powdery)	Bath contamination (iron/carbonate), imbalance	Bath control; decant/replace
Rusts soon after coating	Seal skipped/poor; caustic or water trapped under seal	Verify post-rinse (no caustic), dry/warm before sealing, confirm seal applied
Uneven/blotchy color	Uneven cleaning, caustic drag/dry-on, drag-in	Improve cleaning & rinsing; move parts promptly
Bath surges / spits	Water entering the hot bath	Back away, get lead — eruption risk; find and stop the water source

TIP

Read the part **backward through the line**. Brown/red smut and rub-off → bath chemistry (iron/carbonate/oxidizer/concentration). Gray/patchy/bare → cleaning and pickle. Rust after coating → post-rinse, drying, and the seal. The defect points to the stage that was supposed to prepare for it.

HEADS-UP

Before you change bath chemistry, temperature, or make any addition, confirm with your lead and the supplier program — and remember the oxidizers and the water-addition rule. Bath adjustments are made only by authorized personnel, in full PPE, with ventilation running, slow and clear of the splash zone.

— YOUR DECODER RING

GLOSSARY — EVERY TERM, PLAIN AND SIMPLE

ANYTIME A WORD IN THIS MANUAL MADE YOU PAUSE, FLIP BACK HERE

Black oxide: A blackening conversion coating on steel; in the hot/mid processes it's **magnetite (Fe₃O₄)**.

Magnetite (Fe₃O₄): Black iron oxide; the coating grown by hot/mid black oxide; the same black oxide as lodestone and anvil scale.

Conversion coating: A coating made by reacting the metal's own surface with a chemical solution (no electricity).

Caustic / sodium hydroxide (NaOH): The strong alkali that makes up the hot bath; burns skin/eyes.

Nitrate / nitrite: The **oxidizers** in the hot/mid bath that drive iron to magnetite.

Boiling-point elevation: Dissolving lots of salt (caustic) raises water's boiling point; why the bath boils at ~290°F.

Steam-flash / eruption: Water hitting the super-hot bath instantly turns to steam and throws caustic out of the tank.

Selenium-based (cold) blackening: The room-temperature process; deposits a **selenide film, not magnetite**; faster but less durable; selenium is toxic/regulated.

Dimensional neutrality: Black oxide adds almost no thickness (~0.5–2.5 µm), so parts stay essentially the same size.

Red haze / brown smut: Reddish/brown film or powder from an out-of-balance/old bath, high iron/carbonate, poor cleaning, or short dwell.

Rub-off / smut: Loose powder on the surface; light pre-seal smut can be normal, heavy rub-off is a defect.

Seal (oil/wax/lacquer): The mandatory finish that fills the pores, provides corrosion protection, and deepens the black.

Pickle: An acid dip that strips rust/scale to bright steel before blackening.

Water-break test: Pull a cleaned part; continuous water sheet = clean, beading = oily.

Drag-out / drag-in: Solution carried out of one tank (out) and into the next (in) on the part's surface.

Conductivity (µS/cm): "The contamination number" for rinse water; lower = cleaner.

Hydrogen embrittlement: Loss of ductility in high-strength steel from absorbed hydrogen during acid pickling; may need a relief bake.

MIL-DTL-13924 / AMS 2485 / ASTM D769: The principal black-oxide specs (military / aerospace / historical ASTM).

LOTO (Lockout/Tagout): De-energizing and locking equipment before maintenance.

Substrate: The base metal being coated (here, carbon/alloy/cast/hardened steel).

TDS / SDS: Technical Data Sheet (how to run a product) / Safety Data Sheet (its hazards). Always follow both.

— TEMPLATE — PRINT ONE PER OPERATOR

OPERATOR TRAINING MATRIX

HOW A SUPERVISOR PROVES — ON PAPER — THAT EACH OPERATOR IS TRAINED AND SIGNED OFF BEFORE RUNNING SOLO

REMEMBER

An operator is “line-qualified” only when every station they run is signed. **Nobody works the boiling caustic black oxide bath, makes water/chemistry additions, handles the oxidizers or acid pickle, or does any solo work until the Safety / PPE & SDS row AND the boiling-caustic/water-flash row are signed.** Safety qualification comes first, always.

Sign-off levels: **O** = Observed only · **A** = Assisted under supervision · **Q** = Qualified to run solo · **T** = Qualified to Train others.

#	STATION / SKILL	O/A/Q/T	TRAINER INIT & DATE	OPERATOR INIT & DATE	RE-CERT DUE
1	Safety / PPE & SDS (all stations)	___	___	___	___
2	Boiling-caustic handling & water-flash/eruption control (285–310°F)	___	___	___	___
3	Station 01 — Inspect & Load (drainage, substrate, no trapped water)	___	___	___	___
4	Station 02 — Alkaline Clean + water-break test	___	___	___	___
5	Station 03 — Rinse (post-clean) + conductivity	___	___	___	___
6	Station 04 — Acid Pickle/Descal + embrittlement awareness	___	___	___	___
7	Station 05 — Rinse (post-pickle, acid→caustic firewall)	___	___	___	___
8	Station 06 — Black Oxide (hot) + color/coverage reading	___	___	___	___
9	Bath control — concentration, oxidizer, iron/carbonate , temperature	___	___	___	___
10	Safe water additions to the hot bath (per procedure)	___	___	___	___
11	Nitrate/nitrite oxidizer handling	___	___	___	___
12	Caustic-mist / respiratory awareness & ventilation	___	___	___	___
13	Station 07 — Rinse (post-black-oxide, cold+hot, caustic removal)	___	___	___	___
14	Station 08 — Oil/Wax/Lacquer Seal (mandatory) + fire/mist control	___	___	___	___
15	Station 09 — Inspect & Hand-Off (color/coverage/rub-off/seal)	___	___	___	___
16	Corrosion/salt-spray testing with seal applied	___	___	___	___
17	LOTO (pumps/heaters/hoists/filters/ventilation)	___	___	___	___
18	Emergency response — eyewash, shower, caustic burn , eruption, oil fire	___	___	___	___
19	Waste — caustic neutralization, nitrate/nitrite, selenium (cold) , oil	___	___	___	___
20	Troubleshooting — red haze/brown smut/rub-off/poor-black (read backward)	___	___	___	___

Operator name: _____ Hire/start date: _____ Supervisor: _____ Review: ☐ Annual ☐ Other

HEADS-UP

Safety rows (1, 2, 10, 11, 12, 17, 18) are not optional and not “fill in later.” An operator may not work *any* station until PPE/SDS, **boiling-caustic/water-flash control**, safe water additions, oxidizer handling, caustic-mist awareness, LOTO, and emergency response are signed. Safety competency comes before production competency, always.

PART FOUR — BACK MATTER & CERTIFICATION
20 QUESTIONS • PASSING SCORE 80% (16/20)

BLACK OXIDE COMPLETION TEST

COVERS EVERY STATION PLUS SAFETY — ANSWER IN YOUR OWN WORDS WHERE ASKED

REMEMBER

Passing score: 80% (16 of 20 correct). Any **safety** question answered wrong (Q5, Q6, Q15, Q19) is an automatic fail of the safety gate — re-teach and re-test before sign-off, regardless of total score. The Answer Key follows — no peeking until you're done!

Name: _____ Date: _____ Score: _____ / 20 **Safety-gate Qs (all correct): 5, 6, 15, 19**

Q1. A black oxide coating forms by:

- A. An electric current depositing iron from a bath onto the part B. A chemical reaction between the steel surface and the process solution (no electric current) C. Spraying molten metal onto the steel D. Baking a black powder onto the part in an oven

Q2. (Short answer) What is the **water-break test**, and what result tells you a part is clean?

Q3. In the hot and mid-temperature processes, black oxide on steel is chemically:

- A. Hexavalent chromium B. Electroplated nickel C. Magnetite — black iron oxide (Fe_3O_4) grown from the steel surface D. A layer of paint

Q4. (Short answer) Name **three** typical uses of black oxide on steel, and state whether it is normally used as a paint base.

Q5. [SAFETY GATE] The hot black oxide **bath itself** is hazardous mainly because:

- A. It is radioactive B. It is flammable like gasoline C. It is a near-room-temperature, harmless solution D. It is boiling concentrated caustic at ~285–310°F — hotter than boiling water — causing severe chemical-and-thermal burns, and water entering it flashes to steam and can erupt the tank

Q6. [SAFETY GATE] The correct way to add water to a hot caustic black oxide bath is:

- A. Dump it in quickly to cool the bath fast B. Pour it in from a height to mix well C. Spray it across the surface with a hose D. Add it slowly, in small amounts, per written procedure, while standing clear of the splash zone — because water flashes to steam and can erupt the bath

Q7. (Short answer) What does “dimensionally neutral” mean for black oxide, and why is it a selling point versus plating?

Q8. The hot black oxide bath operates at about:

- A. ~285–310°F (141–154°C) — hotter than boiling water B. Room temperature (no heat) C. ~120–140°F (barely warm) D. Below freezing

Q9. (Short answer) Why does the hot black oxide bath boil *above* water's 212°F — and why does that make water dripped into it so dangerous?

Q10. The corrosion resistance of **bare, unsealed** black oxide is:

- A. Excellent — better than zinc plating B. Minimal — it will rust; the oil/wax/lacquer seal provides the corrosion protection C. Permanent and needs no seal D. Provided entirely by the magnetite, so no oil is needed

Q11. (Short answer) Why is the **oil/wax/lacquer seal mandatory** on black oxide? What does the seal actually do?

Q12. The room-temperature (“cold”) black oxide process:

- A. Deposits a selenium-based film — NOT true magnetite — and is faster but thinner/less durable B. Grows thicker, tougher magnetite than the hot process C. Uses boiling caustic like the hot process D. Requires no chemicals at all

Q13. The mid-temperature black oxide process (~200–250°F):

- A. Deposits a selenium film like the cold process B. Is an electroplating process C. Still grows true magnetite, with less caustic fuming than the boiling hot bath D. Runs hotter than the hot process

Q14. (Short answer) What is **red haze** / **brown smut**, and name two likely causes.

Q15. [SAFETY GATE] The alkaline cleaner stage is hazardous mainly because it is:

- A. Radioactive B. Hot and caustic — it causes chemical burns and its mist irritates the airways C. Explosive on contact with air D. Completely harmless

Q16. A salt-spray / corrosion test on a black-oxidized part should be run:

- A. On the bare oxide only, before any oil B. Without any seal, to test the magnetite alone C. It doesn't matter whether the part is sealed D. On the part WITH the oil/wax/lacquer seal applied — because “black oxide + seal” is the actual product

Q17. (Short answer) In plain terms, how does black oxide form on steel **without any electric current**? (Two or three sentences.)

Q18. Compared with electroplating or phosphate coatings, black oxide is:

- A. Much thicker and adds significant size B. An electroplated metal layer that builds up C. Very thin (~0.5–2.5 µm) and essentially dimensionally neutral — it adds almost no measurable size D. A heavy paint primer

SAFETY SECTION — MUST BE CORRECT TO CERTIFY

Questions 5, 6, 15, and 19 cover hazards that can permanently harm you or others. A miss on any safety item means re-teach and re-test before sign-off.

Q19. (Short answer / Safety) [SAFETY GATE] List **four** pieces of PPE you must wear at the **hot black oxide bath** / **alkaline cleaner** stations, and name **one** additional control required because the **bath is boiling caustic (scald + water-flash eruption)** and the **accelerators are oxidizers**.

Q20. (Short answer) Name **two** honest **tradeoffs/weaknesses** of black oxide compared with plating or a heavy phosphate coating.

End of test. Hand to your trainer for grading.

FOR TRAINERS & SELF-CHECKERS

ANSWER KEY

SHORT-ANSWER RESPONSES DON'T NEED TO MATCH WORD-FOR-WORD — LOOK FOR THE KEY CONCEPTS IN BOLD

HEADS-UP

Keep this page out of the trainee's copy. Questions **5, 6, 15, and 19** are safety-critical — any wrong answer there requires re-training on that topic before sign-off, regardless of total score.

Self-check answer distribution (the 11 multiple-choice items): A = 2, B = 3, C = 3, D = 3. If your key clusters on one letter, you've mis-keyed.

Q1. B — A chemical reaction between the steel surface and the solution; **no electric current**.

Q2. Pull the part and watch the water: a **continuous, unbroken sheet** = clean; **beading** = oil remains, re-clean. (Free — use it every load.)

Q3. C — **Magnetite, Fe₃O₄** (black iron oxide), grown from the steel surface in the hot/mid processes.

Q4. Any three of: tools/drill bits, fasteners, firearms, gears/bearings/precision parts, automotive hardware, optical/anti-glare parts. Black oxide is **NOT** normally a paint base (decorative/anti-glare/mild-corrosion/dimensionally-neutral).

Q5. D — Boiling concentrated caustic at ~285–310°F: severe chemical + thermal burns, and water entering flashes to steam and can erupt the tank. (Handle slowly with a hoist, keep water away, keep back, ventilate, face shield.)

Q6. D — Slowly, small amounts, per written procedure, clear of the splash zone — never a fast dump or hose, because water flashes to steam and can erupt the bath.

Q7. Black oxide adds almost no thickness (~0.5–2.5 µm) and grows partly into the steel, so the part stays essentially the **same size**. Unlike plating (which builds up and can throw tight-tolerance parts out of spec), black oxide can finish precision parts (gears, gauges, fine threads) without changing the fit.

Q8. A — ~285–310°F (141–154°C); hotter than boiling water.

Q9. The bath is **concentrated caustic**, and dissolved salt **raises the boiling point** (boiling-point elevation), so it boils well above 212°F. Because it's far above water's boiling point, **any water that contacts it instantly flashes to steam and can erupt boiling caustic out of the tank**.

Q10. B — Minimal; bare black oxide will rust. The **oil/wax/lacquer seal provides the corrosion protection**.

Q11. Bare magnetite is thin and **porous** and gives minimal corrosion resistance — so the **seal is mandatory**. The oil/wax/lacquer **fills the pores, provides the corrosion protection, and deepens the black**. "Black oxide + seal" is the actual product (and how the specs are written).

Q12. A — Cold/room-temp blackening deposits a **selenium-based film, not true magnetite**; faster and needs no heat but is thinner, less durable, and less abrasion/corrosion resistant (and selenium waste is regulated).

Q13. C — Mid-temperature (~200–250°F) still grows **true magnetite**, with **less caustic fuming** than the boiling hot bath.

Q14. Red haze / brown smut is a reddish or brown film/powder on the part — the bath grew the *wrong* iron oxide or left residue. Any two causes: **low concentration, low oxidizer, exhausted/old bath, high dissolved iron or carbonate, poor cleaning, or too-short dwell** (also poor rinsing).

Q15. B — Hot and caustic; causes chemical burns and its mist irritates the airways. (Required PPE + ventilation.)

Q16. D — With the **oil/wax/lacquer seal applied**. Bare magnetite fails almost immediately by design; the corrosion spec describes the sealed product.

Q17. The **hot caustic** attacks surface iron and takes it into solution; the **nitrate/nitrite oxidizers** control how far the iron is oxidized; **black magnetite (Fe₃O₄) precipitates** onto the surface where the bare steel was. No electricity — the hot caustic and oxidizers do it themselves.

Q18. C — Very thin (~0.5–2.5 µm) and essentially **dimensionally neutral** — adds almost no measurable size (unlike plating, which builds up).

Q19. PPE (any four): sealed chemical splash goggles, **face shield**, caustic- and **heat-resistant** gloves, chemical apron, chemical-resistant/non-slip boots, respirator if ventilation is inadequate. **Hot-bath/oxidizer control (any one):** lower/raise baskets slowly with a hoist (never drop parts in or lean over the boiling bath); **never add water fast / keep all water away from the tank** (eruption risk); run local exhaust for steam/caustic mist; keep nitrate/nitrite oxidizers away from fuels/oils/rags; make additions only per procedure, clear of the splash zone.

Q20. Any two of: **bare coating gives minimal corrosion resistance — seal is mandatory; even sealed, corrosion protection is modest** (not for harsh outdoor/marine service); **the hot bath is a severe boiling-caustic/eruption hazard and energy-hungry**; **steel/iron only** (stainless/copper/zinc need different chemistry); **not a paint base; regulated caustic/nitrate/oil (and selenium for cold) waste**.

REMEMBER

16/20 passes — but every safety question (5, 6, 15, 19) must be correct to certify. Miss a safety item → re-teach and re-test before sign-off. We don't gamble with people.

BLACK OXIDE (STEEL) COATING TRAINING PROGRAM

This certifies that

OPERATOR NAME

has successfully completed the **Black Oxide (Steel)** training course — covering all nine process stations (Inspect/Load, Alkaline Clean, Rinse, Acid Pickle/Descale, Rinse, **Black Oxide [hot caustic-nitrate]**, Rinse, **Oil/Wax/Lacquer Seal**, and Inspect/Hand-Off), the fundamentals of chemical conversion coating without electric current, the **black magnetite (Fe₃O₄)** nature of the coating and its **dimensional neutrality**, the **three temperature classes (hot, mid-temperature, and the selenium-based cold process)**, why the **oil/wax/lacquer seal is mandatory** and does the corrosion protecting, the decorative and **anti-glare** uses, bath control (concentration, oxidizer, iron/carbonate, temperature), red-haze/brown-smut troubleshooting, quality checks including corrosion testing **with the seal applied**, the specs (**MIL-DTL-13924, AMS 2485, ASTM D769**), waste handling (caustic, nitrate/nitrite, selenium, oil), and the safety practices for **the boiling concentrated caustic bath (~285–310°F) — severe scald + chemical burns and the water-flashing-to-steam eruption hazard** — hot alkaline cleaners, the acid pickle, the nitrate/nitrite oxidizers, caustic mist, and the oil/lacquer seal's flammability/hot-oil hazards — and has passed the Completion Test with a score of _____ / 20, including all required safety competencies.

This operator is hereby cleared for **independent work** at the certified stations listed on the Operator Training Matrix.

Date of completion: _____ Re-certification due: _____

TRAINEE SIGNATURE

CERTIFYING TRAINER

SUPERVISOR

Training reference only. Verify all parameters against your chemistry supplier's TDS, customer specifications, and applicable regulatory requirements before production use. The hot black oxide bath is boiling concentrated caustic — treat scald, chemical burns, and the water-flash eruption as the primary hazards; keep water away from the hot bath; nitrate/nitrite are oxidizers; the cold process uses regulated selenium; seal oils/lacquers are combustible. Always consult current SDS and comply with OSHA, EPA, REACH, and local regulations.
